GETTING STARTED

1	Documentation	3
2	Indices and tables	205
	Python Module Index	207
	Index	209

vLLM is a fast and easy-to-use library for LLM inference and serving.

vLLM is fast with:

- State-of-the-art serving throughput
- Efficient management of attention key and value memory with **PagedAttention**
- Continuous batching of incoming requests
- Fast model execution with CUDA/HIP graph
- Quantization: [GPTQ](#), [AWQ](#), INT4, INT8, and FP8
- Optimized CUDA kernels, including integration with FlashAttention and FlashInfer.
- Speculative decoding
- Chunked prefill

vLLM is flexible and easy to use with:

- Seamless integration with popular HuggingFace models
- High-throughput serving with various decoding algorithms, including *parallel sampling*, *beam search*, and more
- Tensor parallelism and pipeline parallelism support for distributed inference
- Streaming outputs
- OpenAI-compatible API server
- Support NVIDIA GPUs, AMD CPUs and GPUs, Intel CPUs and GPUs, PowerPC CPUs, TPU, and AWS Neuron.
- Prefix caching support
- Multi-lora support

For more information, check out the following:

- [vLLM announcing blog post](#) (intro to PagedAttention)
- [vLLM paper](#) (SOSP 2023)
- [How continuous batching enables 23x throughput in LLM inference while reducing p50 latency](#) by Cade Daniel et al.
- [vLLM Meetups](#).

1.1 Installation

vLLM is a Python library that also contains pre-compiled C++ and CUDA (12.1) binaries.

1.1.1 Requirements

- OS: Linux
- Python: 3.8 – 3.12
- GPU: compute capability 7.0 or higher (e.g., V100, T4, RTX20xx, A100, L4, H100, etc.)

1.1.2 Install with pip

You can install vLLM using pip:

```
$ # (Recommended) Create a new conda environment.
$ conda create -n myenv python=3.10 -y
$ conda activate myenv

$ # Install vLLM with CUDA 12.1.
$ pip install vllm
```

Note: Although we recommend using conda to create and manage Python environments, it is highly recommended to use pip to install vLLM. This is because pip can install torch with separate library packages like NCCL, while conda installs torch with statically linked NCCL. This can cause issues when vLLM tries to use NCCL. See [this issue](#) for more details.

Note: As of now, vLLM's binaries are compiled with CUDA 12.1 and public PyTorch release versions by default. We also provide vLLM binaries compiled with CUDA 11.8 and public PyTorch release versions:

```
$ # Install vLLM with CUDA 11.8.
$ export VLLM_VERSION=0.6.1.post1
$ export PYTHON_VERSION=310
$ pip install https://github.com/vllm-project/vllm/releases/download/v${VLLM_VERSION}/
↪ vllm-${VLLM_VERSION}+cu118-cp${PYTHON_VERSION}-cp${PYTHON_VERSION}-manylinux1_x86_64.
↪ whl --extra-index-url https://download.pytorch.org/whl/cu118
```

In order to be performant, vLLM has to compile many cuda kernels. The compilation unfortunately introduces binary incompatibility with other CUDA versions and PyTorch versions, even for the same PyTorch version with different building configurations.

Therefore, it is recommended to install vLLM with a **fresh new** conda environment. If either you have a different CUDA version or you want to use an existing PyTorch installation, you need to build vLLM from source. See below for instructions.

Note: vLLM also publishes a subset of wheels (Python 3.10, 3.11 with CUDA 12) for every commit since v0.5.3. You can download them with the following command:

```
$ export VLLM_VERSION=0.6.1.post1 # vLLM's main branch version is currently set to latest_
→released tag
$ pip install https://vllm-wheels.s3.us-west-2.amazonaws.com/nightly/vllm-${VLLM_VERSION}
→-cp38-abi3-manylinux1_x86_64.whl
$ # You can also access a specific commit
$ # export VLLM_COMMIT=...
$ # pip install https://vllm-wheels.s3.us-west-2.amazonaws.com/${VLLM_COMMIT}/vllm-$
→{VLLM_VERSION}-cp38-abi3-manylinux1_x86_64.whl
```

1.1.3 Build from source

You can also build and install vLLM from source:

```
$ git clone https://github.com/vllm-project/vllm.git
$ cd vllm
$ pip install -e . # This may take 5-10 minutes.
```

Note: vLLM can fully run only on Linux, but you can still build it on other systems (for example, macOS). This build is only for development purposes, allowing for imports and a more convenient dev environment. The binaries will not be compiled and not work on non-Linux systems. You can create such a build with the following commands:

```
$ export VLLM_TARGET_DEVICE=empty
$ pip install -e .
```

Tip: Building from source requires quite a lot compilation. If you are building from source for multiple times, it is beneficial to cache the compilation results. For example, you can install `ccache` via either `conda install ccache` or `apt install ccache`. As long as `which ccache` command can find the `ccache` binary, it will be used automatically by the build system. After the first build, the subsequent builds will be much faster.

Tip: To avoid your system being overloaded, you can limit the number of compilation jobs to be run simultaneously, via the environment variable `MAX_JOBS`. For example:

```
$ export MAX_JOBS=6
$ pip install -e .
```

Tip: If you have trouble building vLLM, we recommend using the NVIDIA PyTorch Docker image.

```
$ # Use `--ipc=host` to make sure the shared memory is large enough.
$ docker run --gpus all -it --rm --ipc=host nvcr.io/nvidia/pytorch:23.10-py3
```

If you don't want to use docker, it is recommended to have a full installation of CUDA Toolkit. You can download and install it from the [official website](#). After installation, set the environment variable `CUDA_HOME` to the installation path of CUDA Toolkit, and make sure that the `nvcc` compiler is in your `PATH`, e.g.:

```
$ export CUDA_HOME=/usr/local/cuda
$ export PATH="${CUDA_HOME}/bin:$PATH"
```

Here is a sanity check to verify that the CUDA Toolkit is correctly installed:

```
$ nvcc --version # verify that nvcc is in your PATH
$ ${CUDA_HOME}/bin/nvcc --version # verify that nvcc is in your CUDA_HOME
```

1.2 Installation with ROCm

vLLM supports AMD GPUs with ROCm 6.1.

1.2.1 Requirements

- OS: Linux
- Python: 3.8 – 3.11
- GPU: MI200s (gfx90a), MI300 (gfx942), Radeon RX 7900 series (gfx1100)
- ROCm 6.1

Installation options:

1. *Build from source with docker*
2. *Build from source*

1.2.2 Option 1: Build from source with docker (recommended)

You can build and install vLLM from source.

First, build a docker image from [Dockerfile.rocm](#) and launch a docker container from the image.

[Dockerfile.rocm](#) uses ROCm 6.1 by default, but also supports ROCm 5.7 and 6.0 in older vLLM branches. It provides flexibility to customize the build of docker image using the following arguments:

- `BASE_IMAGE`: specifies the base image used when running `docker build`, specifically the PyTorch on ROCm base image.
- `BUILD_FA`: specifies whether to build CK flash-attention. The default is 1. For [Radeon RX 7900 series \(gfx1100\)](#), this should be set to 0 before flash-attention supports this target.
- `FX_GFX_ARCHS`: specifies the GFX architecture that is used to build CK flash-attention, for example, `gfx90a;gfx942` for MI200 and MI300. The default is `gfx90a;gfx942`

- `FA_BRANCH`: specifies the branch used to build the CK flash-attention in [ROCm's flash-attention repo](#). The default is `ae7928c`
- `BUILD_TRITON`: specifies whether to build triton flash-attention. The default value is 1.

Their values can be passed in when running `docker build` with `--build-arg` options.

To build vllm on ROCm 6.1 for MI200 and MI300 series, you can use the default:

```
$ DOCKER_BUILDKIT=1 docker build -f Dockerfile.rocm -t vllm-rocm .
```

To build vllm on ROCm 6.1 for Radeon RX7900 series (gfx1100), you should specify `BUILD_FA` as below:

```
$ DOCKER_BUILDKIT=1 docker build --build-arg BUILD_FA="0" -f Dockerfile.rocm -t vllm-rocm .
```

To run the above docker image `vllm-rocm`, use the below command:

```
$ docker run -it \  
  --network=host \  
  --group-add=video \  
  --ipc=host \  
  --cap-add=SYS_PTRACE \  
  --security-opt seccomp=unconfined \  
  --device /dev/kfd \  
  --device /dev/dri \  
  -v <path/to/model>:/app/model \  
  vllm-rocm \  
  bash
```

Where the `<path/to/model>` is the location where the model is stored, for example, the weights for llama2 or llama3 models.

1.2.3 Option 2: Build from source

0. Install prerequisites (skip if you are already in an environment/docker with the following installed):

- ROCm
- PyTorch
- hipBLAS

For installing PyTorch, you can start from a fresh docker image, e.g, `rocm/pytorch:rocm6.1.2_ubuntu20.04_py3.9_pytorch_staging`, `rocm/pytorch-nightly`.

Alternatively, you can install PyTorch using PyTorch wheels. You can check PyTorch installation guild in [PyTorch Getting Started](#)

1. Install [Triton flash attention for ROCm](#)

Install ROCm's Triton flash attention (the default triton-mlir branch) following the instructions from [ROCm/triton](#)

2. Optionally, if you choose to use CK flash attention, you can install [flash attention for ROCm](#)

Install ROCm's flash attention (v2.5.9.post1) following the instructions from [ROCm/flash-attention](#) Alternatively, wheels intended for vLLM use can be accessed under the releases.

Note:

- You might need to downgrade the “ninja” version to 1.10 if it is not used when compiling flash-attention-2 (e.g. `pip install ninja==1.10.2.4`)

3. Build vLLM.

```
$ cd vllm
$ pip install -U -r requirements-rocm.txt
$ python setup.py develop # This may take 5-10 minutes. Currently, `pip install .` does.
↪not work for ROCm installation
```

Tip: For example, vLLM v0.5.3 on ROCm 6.1 can be built with the following steps:

```
$ pip install --upgrade pip

$ # Install PyTorch
$ pip uninstall torch -y
$ pip install --no-cache-dir --pre torch==2.5.0.dev20240726 --index-url https://download.
↪pytorch.org/whl/nightly/rocm6.1

$ # Build & install AMD SMI
$ pip install /opt/rocm/share/amd_smi

$ # Install dependencies
$ pip install --upgrade numba scipy huggingface-hub[cli]
$ pip install "numpy<2"
$ pip install -r requirements-rocm.txt

$ # Apply the patch to ROCM 6.1 (requires root permission)
$ wget -N https://github.com/ROCm/vllm/raw/fa78403/rocm_patch/libamdhip64.so.6 -P /opt/
↪rocm/lib
$ rm -f "$(python3 -c 'import torch; print(torch.__path__[0])')"/lib/libamdhip64.so*

$ # Build vLLM for MI210/MI250/MI300.
$ export PYTORCH_ROCM_ARCH="gfx90a;gfx942"
$ python3 setup.py develop
```

Tip:

- Triton flash attention is used by default. For benchmarking purposes, it is recommended to run a warm up step before collecting perf numbers.
- Triton flash attention does not currently support sliding window attention. If using half precision, please use CK flash-attention for sliding window support.
- To use CK flash-attention or PyTorch naive attention, please use this flag `export VLLM_USE_TRITON_FLASH_ATTN=0` to turn off triton flash attention.
- The ROCm version of PyTorch, ideally, should match the ROCm driver version.

Tip:

- For MI300x (gfx942) users, to achieve optimal performance, please refer to [MI300x tuning guide](#) for performance optimization and tuning tips on system and workflow level. For vLLM, please refer to [vLLM performance optimization](#).
-

1.3 Installation with OpenVINO

vLLM powered by OpenVINO supports all LLM models from [vLLM supported models list](#) and can perform optimal model serving on all x86-64 CPUs with, at least, AVX2 support. OpenVINO vLLM backend supports the following advanced vLLM features:

- Prefix caching (`--enable-prefix-caching`)
- Chunked prefill (`--enable-chunked-prefill`)

Table of contents:

- [Requirements](#)
- [Quick start using Dockerfile](#)
- [Build from source](#)
- [Performance tips](#)
- [Limitations](#)

1.3.1 Requirements

- OS: Linux
- Instruction set architecture (ISA) requirement: at least AVX2.

1.3.2 Quick start using Dockerfile

```
$ docker build -f Dockerfile.openvino -t vllm-openvino-env .  
$ docker run -it --rm vllm-openvino-env
```

1.3.3 Install from source

- First, install Python. For example, on Ubuntu 22.04, you can run:

```
$ sudo apt-get update -y  
$ sudo apt-get install python3
```

- Second, install prerequisites vLLM OpenVINO backend installation:

```
$ pip install --upgrade pip  
$ pip install -r requirements-build.txt --extra-index-url https://download.pytorch.  
↪org/whl/cpu
```

- Finally, install vLLM with OpenVINO backend:

```
$ PIP_EXTRA_INDEX_URL="https://download.pytorch.org/whl/cpu" VLLM_TARGET_
↪DEVICE=openvino python -m pip install -v .
```

1.3.4 Performance tips

vLLM OpenVINO backend uses the following environment variables to control behavior:

- `VLLM_OPENVINO_KVCACHE_SPACE` to specify the KV Cache size (e.g, `VLLM_OPENVINO_KVCACHE_SPACE=40` means 40 GB space for KV cache), larger setting will allow vLLM running more requests in parallel. This parameter should be set based on the hardware configuration and memory management pattern of users.
- `VLLM_OPENVINO_CPU_KV_CACHE_PRECISION=u8` to control KV cache precision. By default, FP16 / BF16 is used depending on platform.
- `VLLM_OPENVINO_ENABLE_QUANTIZED_WEIGHTS=ON` to enable U8 weights compression during model loading stage. By default, compression is turned off. You can also export model with different compression techniques using *optimum-cli* and pass exported folder as `<model_id>`

To enable better TPOT / TTFT latency, you can use vLLM's chunked prefill feature (`--enable-chunked-prefill`). Based on the experiments, the recommended batch size is 256 (`--max-num-batched-tokens`)

OpenVINO best known configuration is:

```
$ VLLM_OPENVINO_KVCACHE_SPACE=100 VLLM_OPENVINO_CPU_KV_CACHE_PRECISION=u8 VLLM_OPENVINO_
↪ENABLE_QUANTIZED_WEIGHTS=ON \
python3 vllm/benchmarks/benchmark_throughput.py --model meta-llama/Llama-2-7b-chat-
↪hf --dataset vllm/benchmarks/ShareGPT_V3_unfiltered_cleaned_split.json --enable-
↪chunked-prefill --max-num-batched-tokens 256
```

1.3.5 Limitations

- LoRA serving is not supported.
- Only LLM models are currently supported. LLaVa and encoder-decoder models are not currently enabled in vLLM OpenVINO integration.
- Tensor and pipeline parallelism are not currently enabled in vLLM integration.

1.4 Installation with CPU

vLLM initially supports basic model inferencing and serving on x86 CPU platform, with data types FP32 and BF16.

Table of contents:

1. *Requirements*
2. *Quick start using Dockerfile*
3. *Build from source*
4. *Related runtime environment variables*
5. *Intel Extension for PyTorch*
6. *Performance tips*

1.4.1 Requirements

- OS: Linux
- Compiler: gcc/g++>=12.3.0 (optional, recommended)
- Instruction set architecture (ISA) requirement: AVX512 (optional, recommended)

1.4.2 Quick start using Dockerfile

```
$ docker build -f Dockerfile.cpu -t vllm-cpu-env --shm-size=4g .
$ docker run -it \
    --rm \
    --network=host \
    --cpuset-cpus=<cpu-id-list, optional> \
    --cpuset-mems=<memory-node, optional> \
    vllm-cpu-env
```

1.4.3 Build from source

- First, install recommended compiler. We recommend to use gcc/g++ >= 12.3.0 as the default compiler to avoid potential problems. For example, on Ubuntu 22.4, you can run:

```
$ sudo apt-get update -y
$ sudo apt-get install -y gcc-12 g++-12 libnuma-dev
$ sudo update-alternatives --install /usr/bin/gcc gcc /usr/bin/gcc-12 10 --slave /usr/
↳bin/g++ g++ /usr/bin/g++-12
```

- Second, install Python packages for vLLM CPU backend building:

```
$ pip install --upgrade pip
$ pip install wheel packaging ninja "setuptools>=49.4.0" numpy
$ pip install -v -r requirements-cpu.txt --extra-index-url https://download.pytorch.org/
↳whl/cpu
```

- Third, build and install oneDNN library from source:

```
$ git clone -b rls-v3.5 https://github.com/oneapi-src/oneDNN.git
$ cmake -B ./oneDNN/build -S ./oneDNN -G Ninja -DONEDNN_LIBRARY_TYPE=STATIC \
    -DONEDNN_BUILD_DOC=OFF \
    -DONEDNN_BUILD_EXAMPLES=OFF \
    -DONEDNN_BUILD_TESTS=OFF \
    -DONEDNN_BUILD_GRAPH=OFF \
    -DONEDNN_ENABLE_WORKLOAD=INFERENCE \
    -DONEDNN_ENABLE_PRIMITIVE=MATMUL
$ cmake --build ./oneDNN/build --target install --config Release
```

- Finally, build and install vLLM CPU backend:

```
$ VLLM_TARGET_DEVICE=cpu python setup.py install
```

Note:

- BF16 is the default data type in the current CPU backend (that means the backend will cast FP16 to BF16), and is compatible with all CPUs with AVX512 ISA support.
- AVX512_BF16 is an extension ISA provides native BF16 data type conversion and vector product instructions, will bring some performance improvement compared with pure AVX512. The CPU backend build script will check the host CPU flags to determine whether to enable AVX512_BF16.
- If you want to force enable AVX512_BF16 for the cross-compilation, please set environment variable `VLLM_CPU_AVX512BF16=1` before the building.

1.4.4 Related runtime environment variables

- `VLLM_CPU_KVCACHE_SPACE`: specify the KV Cache size (e.g, `VLLM_CPU_KVCACHE_SPACE=40` means 40 GB space for KV cache), larger setting will allow vLLM running more requests in parallel. This parameter should be set based on the hardware configuration and memory management pattern of users.
- `VLLM_CPU_OMP_THREADS_BIND`: specify the CPU cores dedicated to the OpenMP threads. For example, `VLLM_CPU_OMP_THREADS_BIND=0-31` means there will be 32 OpenMP threads bound on 0-31 CPU cores. `VLLM_CPU_OMP_THREADS_BIND=0-31|32-63` means there will be 2 tensor parallel processes, 32 OpenMP threads of rank0 are bound on 0-31 CPU cores, and the OpenMP threads of rank1 are bound on 32-63 CPU cores.

1.4.5 Intel Extension for PyTorch

- [Intel Extension for PyTorch \(IPEX\)](#) extends PyTorch with up-to-date features optimizations for an extra performance boost on Intel hardware.

1.4.6 Performance tips

- We highly recommend to use TCMalloc for high performance memory allocation and better cache locality. For example, on Ubuntu 22.4, you can run:

```
$ sudo apt-get install libtcmalloc-minimal4 # install TCMalloc library
$ find / -name *libtcmalloc* # find the dynamic link library path
$ export LD_PRELOAD=/usr/lib/x86_64-linux-gnu/libtcmalloc_minimal.so.4:$LD_PRELOAD #
↪prepend the library to LD_PRELOAD
$ python examples/offline_inference.py # run vLLM
```

- When using the online serving, it is recommended to reserve 1-2 CPU cores for the serving framework to avoid CPU oversubscription. For example, on a platform with 32 physical CPU cores, reserving CPU 30 and 31 for the framework and using CPU 0-29 for OpenMP:

```
$ export VLLM_CPU_KVCACHE_SPACE=40
$ export VLLM_CPU_OMP_THREADS_BIND=0-29
$ vllm serve facebook/opt-125m
```

- If using vLLM CPU backend on a machine with hyper-threading, it is recommended to bind only one OpenMP thread on each physical CPU core using `VLLM_CPU_OMP_THREADS_BIND`. On a hyper-threading enabled platform with 16 logical CPU cores / 8 physical CPU cores:

```

$ lscpu -e # check the mapping between logical CPU cores and physical CPU cores

# The "CPU" column means the logical CPU core IDs, and the "CORE" column means the
↳ physical core IDs. On this platform, two logical cores are sharing one physical core.
CPU NODE SOCKET CORE L1d:L1i:L2:L3 ONLINE   MAXMHZ   MINMHZ   MHZ
0     0     0     0 0:0:0:0       yes 2401.0000 800.0000 800.000
1     0     0     1 1:1:1:0       yes 2401.0000 800.0000 800.000
2     0     0     2 2:2:2:0       yes 2401.0000 800.0000 800.000
3     0     0     3 3:3:3:0       yes 2401.0000 800.0000 800.000
4     0     0     4 4:4:4:0       yes 2401.0000 800.0000 800.000
5     0     0     5 5:5:5:0       yes 2401.0000 800.0000 800.000

7     0     0     7 7:7:7:0       yes 2401.0000 800.0000 800.000
8     0     0     0 0:0:0:0       yes 2401.0000 800.0000 800.000
9     0     0     1 1:1:1:0       yes 2401.0000 800.0000 800.000
10    0     0     2 2:2:2:0       yes 2401.0000 800.0000 800.000
11    0     0     3 3:3:3:0       yes 2401.0000 800.0000 800.000
12    0     0     4 4:4:4:0       yes 2401.0000 800.0000 800.000
13    0     0     5 5:5:5:0       yes 2401.0000 800.0000 800.000
14    0     0     6 6:6:6:0       yes 2401.0000 800.0000 800.000
15    0     0     7 7:7:7:0       yes 2401.0000 800.0000 800.000

# On this platform, it is recommend to only bind openMP threads on logical CPU cores 0-7,
↳ or 8-15
$ export VLLM_CPU_OMP_THREADS_BIND=0-7
$ python examples/offline_inference.py

```

- If using vLLM CPU backend on a multi-socket machine with NUMA, be aware to set CPU cores using VLLM_CPU_OMP_THREADS_BIND to avoid cross NUMA node memory access.

1.5 Installation with Neuron

vLLM 0.3.3 onwards supports model inferencing and serving on AWS Trainium/Inferentia with Neuron SDK. At the moment Paged Attention is not supported in Neuron SDK, but naive continuous batching is supported in transformers-neuronx. Data types currently supported in Neuron SDK are FP16 and BF16.

1.5.1 Requirements

- OS: Linux
- Python: 3.8 – 3.11
- Accelerator: NeuronCore_v2 (in trn1/inf2 instances)
- Pytorch 2.0.1/2.1.1
- AWS Neuron SDK 2.16/2.17 (Verified on python 3.8)

Installation steps:

- *Build from source*
 - *Step 0. Launch Trn1/Inf2 instances*
 - *Step 1. Install drivers and tools*

- *Step 2. Install transformers-neuronx and its dependencies*
- *Step 3. Install vLLM from source*

1.5.2 Build from source

Following instructions are applicable to Neuron SDK 2.16 and beyond.

Step 0. Launch Trn1/Inf2 instances

Here are the steps to launch trn1/inf2 instances, in order to install PyTorch Neuron (“torch-neuronx”) Setup on Ubuntu 22.04 LTS.

- Please follow the instructions at [launch an Amazon EC2 Instance](#) to launch an instance. When choosing the instance type at the EC2 console, please make sure to select the correct instance type.
- To get more information about instances sizes and pricing see: [Trn1 web page](#), [Inf2 web page](#)
- Select Ubuntu Server 22.04 TLS AMI
- When launching a Trn1/Inf2, please adjust your primary EBS volume size to a minimum of 512GB.
- After launching the instance, follow the instructions in [Connect to your instance](#) to connect to the instance

Step 1. Install drivers and tools

The installation of drivers and tools wouldn’t be necessary, if [Deep Learning AMI Neuron](#) is installed. In case the drivers and tools are not installed on the operating system, follow the steps below:

```
# Configure Linux for Neuron repository updates
. /etc/os-release
sudo tee /etc/apt/sources.list.d/neuron.list > /dev/null <<EOF
deb https://apt.repos.neuron.amazonaws.com ${VERSION_CODENAME} main
EOF
wget -q0 - https://apt.repos.neuron.amazonaws.com/GPG-PUB-KEY-AMAZON-AWS-NEURON.PUB |_
↪sudo apt-key add -

# Update OS packages
sudo apt-get update -y

# Install OS headers
sudo apt-get install linux-headers-$(uname -r) -y

# Install git
sudo apt-get install git -y

# install Neuron Driver
sudo apt-get install aws-neuronx-dkms=2.* -y

# Install Neuron Runtime
sudo apt-get install aws-neuronx-collectives=2.* -y
sudo apt-get install aws-neuronx-runtime-lib=2.* -y

# Install Neuron Tools
```

(continues on next page)

```
sudo apt-get install aws-neuronx-tools=2.* -y

# Add PATH
export PATH=/opt/aws/neuron/bin:$PATH
```

Step 2. Install transformers-neuronx and its dependencies

`transformers-neuronx` will be the backend to support inference on trn1/inf2 instances. Follow the steps below to install `transformer-neuronx` package and its dependencies.

```
# Install Python venv
sudo apt-get install -y python3.10-venv g++

# Create Python venv
python3.10 -m venv aws_neuron_venv_pytorch

# Activate Python venv
source aws_neuron_venv_pytorch/bin/activate

# Install Jupyter notebook kernel
pip install ipykernel
python3.10 -m ipykernel install --user --name aws_neuron_venv_pytorch --display-name
↳ "Python (torch-neuronx)"
pip install jupyter notebook
pip install environment_kernels

# Set pip repository pointing to the Neuron repository
python -m pip config set global.extra-index-url https://pip.repos.neuron.amazonaws.com

# Install wget, awscli
python -m pip install wget
python -m pip install awscli

# Update Neuron Compiler and Framework
python -m pip install --upgrade neuronx-cc==2.* --pre torch-neuronx==2.1.* torchvision_
↳ transformers-neuronx
```

Step 3. Install vLLM from source

Once `neuronx-cc` and `transformers-neuronx` packages are installed, we will be able to install `vllm` as follows:

```
$ git clone https://github.com/vllm-project/vllm.git
$ cd vllm
$ pip install -U -r requirements-neuron.txt
$ VLLM_TARGET_DEVICE="neuron" pip install .
```

If `neuron` packages are detected correctly in the installation process, `vllm-0.3.0+neuron212` will be installed.

1.6 Installation with TPU

vLLM supports Google Cloud TPUs using PyTorch XLA.

1.6.1 Requirements

- Google Cloud TPU VM (single & multi host)
- TPU versions: v5e, v5p, v4
- Python: 3.10

Installation options:

1. *Build a docker image with Dockerfile.*
2. *Build from source.*

1.6.2 Build a docker image with Dockerfile.tpu

Dockerfile.tpu is provided to build a docker image with TPU support.

```
$ docker build -f Dockerfile.tpu -t vllm-tpu .
```

You can run the docker image with the following command:

```
$ # Make sure to add `--privileged --net host --shm-size=16G`.
$ docker run --privileged --net host --shm-size=16G -it vllm-tpu
```

1.6.3 Build from source

You can also build and install the TPU backend from source.

First, install the dependencies:

```
$ # (Recommended) Create a new conda environment.
$ conda create -n myenv python=3.10 -y
$ conda activate myenv

$ # Clean up the existing torch and torch-xla packages.
$ pip uninstall torch torch-xla -y

$ # Install PyTorch and PyTorch XLA.
$ export DATE="20240828"
$ export TORCH_VERSION="2.5.0"
$ pip install https://storage.googleapis.com/pytorch-xla-releases/wheels/tpuvvm/torch-$
↪{TORCH_VERSION}.dev${DATE}-cp310-cp310-linux_x86_64.whl
$ pip install https://storage.googleapis.com/pytorch-xla-releases/wheels/tpuvvm/torch_xla-
↪${TORCH_VERSION}.dev${DATE}-cp310-cp310-linux_x86_64.whl

$ # Install JAX and Pallas.
$ pip install torch_xla[tpu] -f https://storage.googleapis.com/libtpu-releases/index.html
$ pip install torch_xla[pallas] -f https://storage.googleapis.com/jax-releases/jax_
```

(continues on next page)

(continued from previous page)

```
↪nightly_releases.html -f https://storage.googleapis.com/jax-releases/jaxlib_nightly_
↪releases.html

$ # Install other build dependencies.
$ pip install -r requirements-tpu.txt
```

Next, build vLLM from source. This will only take a few seconds:

```
$ VLLM_TARGET_DEVICE="tpu" python setup.py develop
```

Note: Since TPU relies on XLA which requires static shapes, vLLM bucketizes the possible input shapes and compiles an XLA graph for each different shape. The compilation time may take 20~30 minutes in the first run. However, the compilation time reduces to ~5 minutes afterwards because the XLA graphs are cached in the disk (in `VLLM_XLA_CACHE_PATH` or `~/.cache/vllm/xla_cache` by default).

Tip: If you encounter the following error:

```
from torch._C import * # noqa: F403
ImportError: libopenblas.so.0: cannot open shared object file: No such file or directory
```

Please install OpenBLAS with the following command:

```
$ sudo apt-get install libopenblas-base libopenmpi-dev libomp-dev
```

1.7 Installation with XPU

vLLM initially supports basic model inferencing and serving on Intel GPU platform.

Table of contents:

1. *Requirements*
2. *Quick start using Dockerfile*
3. *Build from source*

1.7.1 Requirements

- OS: Linux
- Supported Hardware: Intel Data Center GPU (Intel ARC GPU WIP)
- OneAPI requirements: oneAPI 2024.1

1.7.2 Quick start using Dockerfile

```
$ docker build -f Dockerfile.xpu -t vllm-xpu-env --shm-size=4g .
$ docker run -it \
  --rm \
  --network=host \
  --device /dev/dri \
  -v /dev/dri/by-path:/dev/dri/by-path \
  vllm-xpu-env
```

1.7.3 Build from source

- First, install required driver and intel OneAPI 2024.1 or later.
- Second, install Python packages for vLLM XPU backend building:

```
$ source /opt/intel/oneapi/setvars.sh
$ pip install --upgrade pip
$ pip install -v -r requirements-xpu.txt
```

- Finally, build and install vLLM XPU backend:

```
$ VLLM_TARGET_DEVICE=xpu python setup.py install
```

Note:

- FP16 is the default data type in the current XPU backend. The BF16 data type will be supported in the future.

1.8 Quickstart

This guide shows how to use vLLM to:

- run offline batched inference on a dataset;
- build an API server for a large language model;
- start an OpenAI-compatible API server.

Be sure to complete the *installation instructions* before continuing with this guide.

Note: By default, vLLM downloads model from [HuggingFace](#). If you would like to use models from [ModelScope](#) in the following examples, please set the environment variable:

```
export VLLM_USE_MODELSCOPE=True
```

1.8.1 Offline Batched Inference

We first show an example of using vLLM for offline batched inference on a dataset. In other words, we use vLLM to generate texts for a list of input prompts.

Import `LLM` and `SamplingParams` from vLLM. The `LLM` class is the main class for running offline inference with vLLM engine. The `SamplingParams` class specifies the parameters for the sampling process.

```
from vllm import LLM, SamplingParams
```

Define the list of input prompts and the sampling parameters for generation. The sampling temperature is set to 0.8 and the nucleus sampling probability is set to 0.95. For more information about the sampling parameters, refer to the [class definition](#).

```
prompts = [
    "Hello, my name is",
    "The president of the United States is",
    "The capital of France is",
    "The future of AI is",
]
sampling_params = SamplingParams(temperature=0.8, top_p=0.95)
```

Initialize vLLM's engine for offline inference with the `LLM` class and the `OPT-125M` model. The list of supported models can be found at [supported models](#).

```
llm = LLM(model="facebook/opt-125m")
```

Call `llm.generate` to generate the outputs. It adds the input prompts to vLLM engine's waiting queue and executes the vLLM engine to generate the outputs with high throughput. The outputs are returned as a list of `RequestOutput` objects, which include all the output tokens.

```
outputs = llm.generate(prompts, sampling_params)

# Print the outputs.
for output in outputs:
    prompt = output.prompt
    generated_text = output.outputs[0].text
    print(f"Prompt: {prompt!r}, Generated text: {generated_text!r}")
```

The code example can also be found in [examples/offline_inference.py](#).

1.8.2 OpenAI-Compatible Server

vLLM can be deployed as a server that implements the OpenAI API protocol. This allows vLLM to be used as a drop-in replacement for applications using OpenAI API. By default, it starts the server at `http://localhost:8000`. You can specify the address with `--host` and `--port` arguments. The server currently hosts one model at a time (`OPT-125M` in the command below) and implements [list models](#), [create chat completion](#), and [create completion](#) endpoints. We are actively adding support for more endpoints.

Start the server:

```
$ vllm serve facebook/opt-125m
```

By default, the server uses a predefined chat template stored in the tokenizer. You can override this template by using the `--chat-template` argument:

```
$ vllm serve facebook/opt-125m --chat-template ./examples/template_chatml.jinja
```

This server can be queried in the same format as OpenAI API. For example, list the models:

```
$ curl http://localhost:8000/v1/models
```

You can pass in the argument `--api-key` or environment variable `VLLM_API_KEY` to enable the server to check for API key in the header.

Using OpenAI Completions API with vLLM

Query the model with input prompts:

```
$ curl http://localhost:8000/v1/completions \
$   -H "Content-Type: application/json" \
$   -d '{
$     "model": "facebook/opt-125m",
$     "prompt": "San Francisco is a",
$     "max_tokens": 7,
$     "temperature": 0
$   }'
```

Since this server is compatible with OpenAI API, you can use it as a drop-in replacement for any applications using OpenAI API. For example, another way to query the server is via the `openai` python package:

```
from openai import OpenAI

# Modify OpenAI's API key and API base to use vLLM's API server.
openai_api_key = "EMPTY"
openai_api_base = "http://localhost:8000/v1"
client = OpenAI(
    api_key=openai_api_key,
    base_url=openai_api_base,
)
completion = client.completions.create(model="facebook/opt-125m",
                                       prompt="San Francisco is a")
print("Completion result:", completion)
```

For a more detailed client example, refer to `examples/openai_completion_client.py`.

Using OpenAI Chat API with vLLM

The vLLM server is designed to support the OpenAI Chat API, allowing you to engage in dynamic conversations with the model. The chat interface is a more interactive way to communicate with the model, allowing back-and-forth exchanges that can be stored in the chat history. This is useful for tasks that require context or more detailed explanations.

Querying the model using OpenAI Chat API:

You can use the `create chat completion` endpoint to communicate with the model in a chat-like interface:

```
$ curl http://localhost:8000/v1/chat/completions \
$   -H "Content-Type: application/json" \
```

(continues on next page)

(continued from previous page)

```
$ -d '{
$   "model": "facebook/opt-125m",
$   "messages": [
$     {"role": "system", "content": "You are a helpful assistant."},
$     {"role": "user", "content": "Who won the world series in 2020?"}
$   ]
$ }'
```

Python Client Example:

Using the `openai` python package, you can also communicate with the model in a chat-like manner:

```
from openai import OpenAI
# Set OpenAI's API key and API base to use vLLM's API server.
openai_api_key = "EMPTY"
openai_api_base = "http://localhost:8000/v1"

client = OpenAI(
    api_key=openai_api_key,
    base_url=openai_api_base,
)

chat_response = client.chat.completions.create(
    model="facebook/opt-125m",
    messages=[
        {"role": "system", "content": "You are a helpful assistant."},
        {"role": "user", "content": "Tell me a joke."},
    ]
)
print("Chat response:", chat_response)
```

For more in-depth examples and advanced features of the chat API, you can refer to the official OpenAI documentation.

1.9 Debugging Tips

1.9.1 Debugging hang/crash issues

When an vLLM instance hangs or crashes, it is very difficult to debug the issue. But wait a minute, it is also possible that vLLM is doing something that indeed takes a long time:

- **Downloading a model:** Do you have the model already downloaded in your disk? If not, vLLM will download the model from the internet, which can take a long time. Be sure to check the internet connection. It would be better to download the model first using `huggingface-cli` and then use the local path to the model. This way, you can isolate the issue.
- **Loading the model from disk:** If the model is large, it can take a long time to load the model from disk. Please take care of the location you store the model. Some clusters have shared filesystems across nodes, e.g. distributed filesystem or network filesystem, which can be slow. It would be better to store the model in a local disk. In addition, please also watch the CPU memory usage. When the model is too large, it might take much CPU memory, which can slow down the operating system because it needs to frequently swap memory between the disk and the memory.

- **Tensor parallel inference:** If the model is too large to fit in a single GPU, you might want to use tensor parallelism to split the model across multiple GPUs. In that case, every process will read the whole model and split it into chunks, which makes the disk reading time even longer (proportional to the size of tensor parallelism). You can convert the model checkpoint to a sharded checkpoint using [the provided script](#). The conversion process might take some time, but later you can load the sharded checkpoint much faster. The model loading time should remain constant regardless of the size of tensor parallelism.

If you have already taken care of the above issues, but the vLLM instance still hangs, with CPU and GPU utilization at near zero, it is likely that the vLLM instance is stuck somewhere. Here are some tips to help debug the issue:

- Set the environment variable `export VLLM_LOGGING_LEVEL=DEBUG` to turn on more logging.
- Set the environment variable `export CUDA_LAUNCH_BLOCKING=1` to know exactly which CUDA kernel is causing the trouble.
- Set the environment variable `export NCCL_DEBUG=TRACE` to turn on more logging for NCCL.
- Set the environment variable `export VLLM_TRACE_FUNCTION=1`. All the function calls in vLLM will be recorded. Inspect these log files, and tell which function crashes or hangs.

With more logging, hopefully you can find the root cause of the issue.

If it crashes, and the error trace shows somewhere around `self.graph.replay()` in `vllm/worker/model_runner.py`, it is a cuda error inside cudagraph. To know the particular cuda operation that causes the error, you can add `--enforce-eager` to the command line, or `enforce_eager=True` to the `LLM` class, to disable the cudagraph optimization. This way, you can locate the exact cuda operation that causes the error.

Here are some common issues that can cause hangs:

- **Incorrect network setup:** The vLLM instance cannot get the correct IP address if you have complicated network config. You can find the log such as `DEBUG 06-10 21:32:17 parallel_state.py:88] world_size=8 rank=0 local_rank=0 distributed_init_method=tcp://xxx.xxx.xxx.xxx:54641 backend=nccl`. The IP address should be the correct one. If not, override the IP address by setting the environment variable `export VLLM_HOST_IP=your_ip_address`. You might also need to set `export NCCL_SOCKET_IFNAME=your_network_interface` and `export GLOO_SOCKET_IFNAME=your_network_interface` to specify the network interface for the IP address.
- **Incorrect hardware/driver:** GPU/CPU communication cannot be established. You can run the following sanity check script to see if the GPU/CPU communication is working correctly.

```
# Test PyTorch NCCL
import torch
import torch.distributed as dist
dist.init_process_group(backend="nccl")
local_rank = dist.get_rank() % torch.cuda.device_count()
torch.cuda.set_device(local_rank)
data = torch.FloatTensor([1,] * 128).to("cuda")
dist.all_reduce(data, op=dist.ReduceOp.SUM)
torch.cuda.synchronize()
value = data.mean().item()
world_size = dist.get_world_size()
assert value == world_size, f"Expected {world_size}, got {value}"

print("PyTorch NCCL is successful!")

# Test PyTorch GLOO
gloo_group = dist.new_group(ranks=list(range(world_size)), backend="gloo")
cpu_data = torch.FloatTensor([1,] * 128)
```

(continues on next page)

```

dist.all_reduce(cpu_data, op=dist.ReduceOp.SUM, group=gloo_group)
value = cpu_data.mean().item()
assert value == world_size, f"Expected {world_size}, got {value}"

print("PyTorch GL00 is successful!")

# Test vLLM NCCL, with cuda graph
from vllm.distributed.device_communicators.pynccl import PyNcclCommunicator

pynccl = PyNcclCommunicator(group=gloo_group, device=local_rank)
pynccl.disabled = False

s = torch.cuda.Stream()
with torch.cuda.stream(s):
    data.fill_(1)
    pynccl.all_reduce(data, stream=s)
    value = data.mean().item()
    assert value == world_size, f"Expected {world_size}, got {value}"

print("vLLM NCCL is successful!")

g = torch.cuda.CUDAGraph()
with torch.cuda.graph(cuda_graph=g, stream=s):
    pynccl.all_reduce(data, stream=torch.cuda.current_stream())

data.fill_(1)
g.replay()
torch.cuda.current_stream().synchronize()
value = data.mean().item()
assert value == world_size, f"Expected {world_size}, got {value}"

print("vLLM NCCL with cuda graph is successful!")

dist.destroy_process_group(gloo_group)
dist.destroy_process_group()

```

Tip: Save the script as `test.py`.

If you are testing in a single-node, run it with `NCCL_DEBUG=TRACE torchrun --nproc-per-node=8 test.py`, adjust `--nproc-per-node` to the number of GPUs you want to use.

If you are testing with multi-nodes, run it with `NCCL_DEBUG=TRACE torchrun --nnodes 2 --nproc-per-node=2 --rdzv_backend=c10d --rdzv_endpoint=$MASTER_ADDR test.py`. Adjust `--nproc-per-node` and `--nnodes` according to your setup. Make sure `MASTER_ADDR`:

- is the correct IP address of the master node
- is reachable from all nodes
- is set before running the script.

If the script runs successfully, you should see the message `sanity check is successful!`.

If the problem persists, feel free to [open an issue on GitHub](#), with a detailed description of the issue, your environment,

and the logs.

Some known issues:

- In `v0.5.2`, `v0.5.3`, and `v0.5.3.post1`, there is a bug caused by `zmq`, which can cause hangs at a low probability (once in about 20 times, depending on the machine configuration). The solution is to upgrade to the latest version of `vllm` to include the `fix`.

Warning: After you find the root cause and solve the issue, remember to turn off all the debugging environment variables defined above, or simply start a new shell to avoid being affected by the debugging settings. If you don't do this, the system might be slow because many debugging functionalities are turned on.

1.10 Examples

1.10.1 API Client

Source https://github.com/vllm-project/vllm/blob/main/examples/api_client.py.

```

1  """Example Python client for `vllm.entrypoints.api_server`
2  NOTE: The API server is used only for demonstration and simple performance
3  benchmarks. It is not intended for production use.
4  For production use, we recommend `vllm serve` and the OpenAI client API.
5  """

1.10.32 Save Sharded State

Source https://github.com/vllm-project/vllm/blob/main/examples/save_sharded_state.py.

```

1  """
2  Saves each worker's model state dict directly to a checkpoint, which enables a
3  fast load path for large tensor-parallel models where each worker only needs to
4  read its own shard rather than the entire checkpoint.
5
6  Example usage:
7
8  python save_sharded_state.py \
9      --model /path/to/load \
10     --quantization deepspeedfp \
11     --tensor-parallel-size 8 \
12     --output /path/to/save
13
14  Then, the model can be loaded with
15
16  llm = LLM(
17      model="/path/to/save",
18      load_format="sharded_state",
19      quantization="deepspeedfp",
20      tensor_parallel_size=8,
21  )
22  """

13
14 # yapf conflicts with isort for this docstring
15 # yapf: disable
16 """
17 tensorize_vllm_model.py is a script that can be used to serialize and
18 deserialize vLLM models. These models can be loaded using tensorizer
19 to the GPU extremely quickly over an HTTP/HTTPS endpoint, an S3 endpoint,
20 or locally. Tensor encryption and decryption is also supported, although

```

(continues on next page)

(continued from previous page)

21 *libsodium* must be installed to use it. Install *vllm* with *tensorizer* support
 22 using ``pip install vllm[tensorizer]``. To learn more about *tensorizer*, visit
 23 <https://github.com/coreweave/tensorizer>

24
 25 To serialize a model, install *vLLM* from source, then run something
 26 like this from the root level of this repository:

```
27 python -m examples.tensorize_vllm_model \  
28     --model facebook/opt-125m \  
29     serialize \  
30     --serialized-directory s3://my-bucket \  
31     --suffix v1
```

32
 33
 34 Which downloads the model from HuggingFace, loads it into *vLLM*, serializes it,
 35 and saves it to your S3 bucket. A local directory can also be used. This
 36 assumes your S3 credentials are specified as environment variables
 37 in the form of ``S3_ACCESS_KEY_ID``, ``S3_SECRET_ACCESS_KEY``, and
 38 ``S3_ENDPOINT_URL``. To provide S3 credentials directly, you can provide
 39 ``--s3-access-key-id`` and ``--s3-secret-access-key``, as well as ``--s3-endpoint``
 40 as CLI args to this script.

41
 42 You can also encrypt the model weights with a randomly-generated key by
 43 providing a ``--keyfile`` argument.

44
 45 To deserialize a model, you can run something like this from the root
 46 level of this repository:

```
47 python -m examples.tensorize_vllm_model \  
48     --model EleutherAI/gpt-j-6B \  
49     --dtype float16 \  
50     deserialize \  
51     --path-to-tensors s3://my-bucket/vllm/EleutherAI/gpt-j-6B/v1/model.tensors
```

52
 53 Which downloads the model tensors from your S3 bucket and deserializes them.

54
 55 You can also provide a ``--keyfile`` argument to decrypt the model weights if
 56 they were serialized with encryption.

57
 58
 59 To support distributed tensor-parallel models, each model shard will be
 60 serialized to a separate file. The `tensorizer_uri` is then specified as a string
 61 template with a format specifier such as ``%03d`` that will be rendered with the
 62 shard's rank. Sharded models serialized with this script will be named as
 63 `model-rank-%03d.tensors`

64
 65 For more information on the available arguments for serializing, run
 66 ``python -m examples.tensorize_vllm_model serialize --help``.

67
 68 Or for deserializing:

```
69  
70 `python -m examples.tensorize_vllm_model deserialize --help`
```

71
 72 Once a model is serialized, *tensorizer* can be invoked with the ``LLM`` class

(continues on next page)

73 *directly to load models:*

```
74
75     llm = LLM(model="facebook/opt-125m",
76              load_format="tensorizer",
77              model_loader_extra_config=TensorizerConfig(
78                  tensorizer_uri = path_to_tensors,
79                  num_readers=3,
80                  )
81             )
```

82
83 *A serialized model can be used during model loading for the vLLM OpenAI*
84 *inference server. `model_loader_extra_config` is exposed as the CLI arg*
85 *`--model-loader-extra-config`, and accepts a JSON string literal of the*
86 *TensorizerConfig arguments desired.*

87
88 *In order to see all of the available arguments usable to configure*
89 *loading with tensorizer that are given to `TensorizerConfig`, run:*

```
90
91 `python -m examples.tensorize_vllm_model deserialize --help`
```

92
93 *under the `tensorizer options` section. These can also be used for*
94 *deserialization in this example script, although `--tensorizer-uri` and*
95 *`--path-to-tensors` are functionally the same in this case.*

```
96 """
```

```
97
```

```
98
```

```
99 def parse_args():

1.11 OpenAI Compatible Server

vLLM provides an HTTP server that implements OpenAI's [Completions](#) and [Chat API](#).

You can start the server using Python, or using *Docker*:

```
vllm serve NousResearch/Meta-Llama-3-8B-Instruct --dtype auto --api-key token-abc123
```

To call the server, you can use the official OpenAI Python client library, or any other HTTP client.

```

from openai import OpenAI
client = OpenAI(
    base_url="http://localhost:8000/v1",
    api_key="token-abc123",
)

completion = client.chat.completions.create(
    model="NousResearch/Meta-Llama-3-8B-Instruct",
    messages=[
        {"role": "user", "content": "Hello!"}
    ]
)

print(completion.choices[0].message)

```

1.11.1 API Reference

Please see the [OpenAI API Reference](#) for more information on the API. We support all parameters except:

- Chat: tools, and tool_choice.
- Completions: suffix.

vLLM also provides experimental support for OpenAI Vision API compatible inference. See more details in [Using VLMs](#).

1.11.2 Extra Parameters

vLLM supports a set of parameters that are not part of the OpenAI API. In order to use them, you can pass them as extra parameters in the OpenAI client. Or directly merge them into the JSON payload if you are using HTTP call directly.

```
completion = client.chat.completions.create(
    model="NousResearch/Meta-Llama-3-8B-Instruct",
    messages=[
        {"role": "user", "content": "Classify this sentiment: vLLM is wonderful!"}
    ],
    extra_body={
        "guided_choice": ["positive", "negative"]
    }
)
```

Extra Parameters for Chat API

The following *sampling parameters* ([click through to see documentation](#)) are supported.

```
best_of: Optional[int] = None
use_beam_search: bool = False
top_k: int = -1
min_p: float = 0.0
repetition_penalty: float = 1.0
length_penalty: float = 1.0
early_stopping: bool = False
stop_token_ids: Optional[List[int]] = Field(default_factory=list)
include_stop_str_in_output: bool = False
ignore_eos: bool = False
min_tokens: int = 0
skip_special_tokens: bool = True
spaces_between_special_tokens: bool = True
truncate_prompt_tokens: Optional[Annotated[int, Field(ge=1)]] = None
prompt_logprobs: Optional[int] = None
```

The following extra parameters are supported:

```
echo: bool = Field(
    default=False,
    description=(
        "If true, the new message will be prepended with the last message "
        "if they belong to the same role."),
)
add_generation_prompt: bool = Field(
    default=True,
    description=(
        "If true, the generation prompt will be added to the chat template. "
        "This is a parameter used by chat template in tokenizer config of the "
        "model."),
)
add_special_tokens: bool = Field(
    default=False,
    description=(
```

(continues on next page)

(continued from previous page)

```

        "If true, special tokens (e.g. BOS) will be added to the prompt "
        "on top of what is added by the chat template. "
        "For most models, the chat template takes care of adding the "
        "special tokens so this should be set to false (as is the "
        "default)."),
    )
documents: Optional[List[Dict[str, str]]] = Field(
    default=None,
    description=(
        "A list of dicts representing documents that will be accessible to "
        "the model if it is performing RAG (retrieval-augmented generation)."
        " If the template does not support RAG, this argument will have no "
        "effect. We recommend that each document should be a dict containing "
        "\"title\" and \"text\" keys."),
    )
chat_template: Optional[str] = Field(
    default=None,
    description=(
        "A Jinja template to use for this conversion. "
        "As of transformers v4.44, default chat template is no longer "
        "allowed, so you must provide a chat template if the tokenizer "
        "does not define one."),
    )
chat_template_kwargs: Optional[Dict[str, Any]] = Field(
    default=None,
    description=(
        "Additional kwargs to pass to the template renderer. "
        "Will be accessible by the chat template."),
    )
guided_json: Optional[Union[str, dict, BaseModel]] = Field(
    default=None,
    description=(
        "If specified, the output will follow the JSON schema."),
    )
guided_regex: Optional[str] = Field(
    default=None,
    description=(
        "If specified, the output will follow the regex pattern."),
    )
guided_choice: Optional[List[str]] = Field(
    default=None,
    description=(
        "If specified, the output will be exactly one of the choices."),
    )
guided_grammar: Optional[str] = Field(
    default=None,
    description=(
        "If specified, the output will follow the context free grammar."),
    )
guided_decoding_backend: Optional[str] = Field(
    default=None,
    description=(
        "If specified, will override the default guided decoding backend "
        "of the server for this specific request. If set, must be either "

```

(continues on next page)

(continued from previous page)

```

        "'outlines' / 'lm-format-enforcer'"))
guided_whitespace_pattern: Optional[str] = Field(
    default=None,
    description=(
        "If specified, will override the default whitespace pattern "
        "for guided json decoding.")

```

Extra Parameters for Completions API

The following *sampling parameters* ([click through to see documentation](#)) are supported.

```

use_beam_search: bool = False
top_k: int = -1
min_p: float = 0.0
repetition_penalty: float = 1.0

```

1.11.3 Chat Template

In order for the language model to support chat protocol, vLLM requires the model to include a chat template in its tokenizer configuration. The chat template is a Jinja2 template that specifies how are roles, messages, and other chat-specific tokens are encoded in the input.

An example chat template for `NousResearch/Meta-Llama-3-8B-Instruct` can be found [here](#)

Some models do not provide a chat template even though they are instruction/chat fine-tuned. For those model, you can manually specify their chat template in the `--chat-template` parameter with the file path to the chat template, or the template in string form. Without a chat template, the server will not be able to process chat and all chat requests will error.

```
vllm serve <model> --chat-template ./path-to-chat-template.jinja
```

vLLM community provides a set of chat templates for popular models. You can find them in the examples directory [here](#)

1.11.4 Command line arguments for the server

```

usage: vllm serve [-h] [--host HOST] [--port PORT]
                 [--uvicorn-log-level {debug,info,warning,error,critical,trace}]
                 [--allow-credentials] [--allowed-origins ALLOWED_ORIGINS]
                 [--allowed-methods ALLOWED_METHODS]
                 [--allowed-headers ALLOWED_HEADERS] [--api-key API_KEY]
                 [--lora-modules LORA_MODULES [LORA_MODULES ...]]
                 [--prompt-adapters PROMPT_ADAPTERS [PROMPT_ADAPTERS ...]]

```

Named Arguments

--host	host name
--port	port number Default: 8000
--uvicorn-log-level	Possible choices: debug, info, warning, error, critical, trace log level for uvicorn Default: “info”
--allow-credentials	allow credentials Default: False

--allowed-origins	allowed origins Default: ['*']
--allowed-methods	allowed methods Default: ['*']
--allowed-headers	allowed headers Default: ['*']
--api-key	If provided, the server will require this key to be presented in the header.
--lora-modules	LoRA module configurations in the format name=path. Multiple modules can be specified.
--prompt-adapters	Prompt adapter configurations in the format name=path. Multiple adapters can be specified.
--chat-template	The file path to the chat template, or the template in single-line form for the specified model
--response-role	The role name to return if <i>request.add_generation_prompt=true</i> . Default: assistant
--ssl-keyfile	The file path to the SSL key file
--ssl-certfile	The file path to the SSL cert file
--ssl-ca-certs	The CA certificates file
--ssl-cert-reqs	Whether client certificate is required (see stdlib ssl module's) Default: 0
--root-path	FastAPI root_path when app is behind a path based routing proxy
--middleware	Additional ASGI middleware to apply to the app. We accept multiple <code>--middleware</code> arguments. The value should be an import path. If a function is provided, vLLM will add it to the server using <code>@app.middleware('http')</code> . If a class is provided, vLLM will add it to the server using <code>app.add_middleware()</code> . Default: []
--return-tokens-as-token-ids	When <code>--max-logprobs</code> is specified, represents single tokens as strings of the form <code>'token_id:{token_id}'</code> so that tokens that are not JSON-encodable can be identified. Default: False
--disable-frontend-multiprocessing	If specified, will run the OpenAI frontend server in the same process as the model serving engine. Default: False
--enable-auto-tool-choice	Enable auto tool choice for supported models. Use <code>--tool-call-parser</code> to specify which parser to use Default: False
--tool-call-parser	Possible choices: mistral, hermes Select the tool call parser depending on the model that you're using. This is used to parse the model-generated tool call into OpenAI API format. Required for <code>--enable-auto-tool-choice</code> .

--model	Name or path of the huggingface model to use. Default: “facebook/opt-125m”
--tokenizer	Name or path of the huggingface tokenizer to use. If unspecified, model name or path will be used.
--skip-tokenizer-init	Skip initialization of tokenizer and detokenizer Default: False
--revision	The specific model version to use. It can be a branch name, a tag name, or a commit id. If unspecified, will use the default version.
--code-revision	The specific revision to use for the model code on Hugging Face Hub. It can be a branch name, a tag name, or a commit id. If unspecified, will use the default version.
--tokenizer-revision	Revision of the huggingface tokenizer to use. It can be a branch name, a tag name, or a commit id. If unspecified, will use the default version.
--tokenizer-mode	Possible choices: auto, slow, mistral The tokenizer mode. <ul style="list-style-type: none"> • “auto” will use the fast tokenizer if available. • “slow” will always use the slow tokenizer. • “mistral” will always use the <i>mistral_common</i> tokenizer. Default: “auto”
--trust-remote-code	Trust remote code from huggingface. Default: False
--download-dir	Directory to download and load the weights, default to the default cache dir of huggingface.
--load-format	Possible choices: auto, pt, safetensors, npcache, dummy, tensorizer, sharded_state, gguf, bitsandbytes, mistral The format of the model weights to load. <ul style="list-style-type: none"> • “auto” will try to load the weights in the safetensors format and fall back to the pytorch bin format if safetensors format is not available. • “pt” will load the weights in the pytorch bin format. • “safetensors” will load the weights in the safetensors format. • “npcache” will load the weights in pytorch format and store a numpy cache to speed up the loading. • “dummy” will initialize the weights with random values, which is mainly for profiling. • “tensorizer” will load the weights using tensorizer from CoreWeave. See the Tensorize vLLM Model script in the Examples section for more information. • “bitsandbytes” will load the weights using bitsandbytes quantization. Default: “auto”
--config-format	Possible choices: auto, hf, mistral The format of the model config to load.

- “auto” will try to load the config in hf format if available else it will try to load in mistral format
- Default: “auto”
- dtype** Possible choices: auto, half, float16, bfloat16, float, float32
- Data type for model weights and activations.
- “auto” will use FP16 precision for FP32 and FP16 models, and BF16 precision for BF16 models.
 - “half” for FP16. Recommended for AWQ quantization.
 - “float16” is the same as “half”.
 - “bfloat16” for a balance between precision and range.
 - “float” is shorthand for FP32 precision.
 - “float32” for FP32 precision.
- Default: “auto”
- kv-cache-dtype** Possible choices: auto, fp8, fp8_e5m2, fp8_e4m3
- Data type for kv cache storage. If “auto”, will use model data type. CUDA 11.8+ supports fp8 (=fp8_e4m3) and fp8_e5m2. ROCm (AMD GPU) supports fp8 (=fp8_e4m3)
- Default: “auto”
- quantization-param-path** Path to the JSON file containing the KV cache scaling factors. This should generally be supplied, when KV cache dtype is FP8. Otherwise, KV cache scaling factors default to 1.0, which may cause accuracy issues. FP8_E5M2 (without scaling) is only supported on cuda version greater than 11.8. On ROCm (AMD GPU), FP8_E4M3 is instead supported for common inference criteria.
- max-model-len** Model context length. If unspecified, will be automatically derived from the model config.
- guided-decoding-backend** Possible choices: outlines, lm-format-enforcer
- Which engine will be used for guided decoding (JSON schema / regex etc) by default. Currently support <https://github.com/outlines-dev/outlines> and <https://github.com/noamgat/lm-format-enforcer>. Can be overridden per request via `guided_decoding_backend` parameter.
- Default: “outlines”
- distributed-executor-backend** Possible choices: ray, mp
- Backend to use for distributed serving. When more than 1 GPU is used, will be automatically set to “ray” if installed or “mp” (multiprocessing) otherwise.
- worker-use-ray** Deprecated, use `--distributed-executor-backend=ray`.
- Default: False
- pipeline-parallel-size, -pp** Number of pipeline stages.
- Default: 1
- tensor-parallel-size, -tp** Number of tensor parallel replicas.
- Default: 1

-
- max-parallel-loading-workers** Load model sequentially in multiple batches, to avoid RAM OOM when using tensor parallel and large models.
- ray-workers-use-nsight** If specified, use nsight to profile Ray workers.
Default: False
- block-size** Possible choices: 8, 16, 32
Token block size for contiguous chunks of tokens. This is ignored on neuron devices and set to max-model-len
Default: 16
- enable-prefix-caching** Enables automatic prefix caching.
Default: False
- disable-sliding-window** Disables sliding window, capping to sliding window size
Default: False
- use-v2-block-manager** Use BlockSpaceMangerV2.
Default: False
- num-lookahead-slots** Experimental scheduling config necessary for speculative decoding. This will be replaced by speculative config in the future; it is present to enable correctness tests until then.
Default: 0
- seed** Random seed for operations.
Default: 0
- swap-space** CPU swap space size (GiB) per GPU.
Default: 4
- cpu-offload-gb** The space in GiB to offload to CPU, per GPU. Default is 0, which means no offloading. Intuitively, this argument can be seen as a virtual way to increase the GPU memory size. For example, if you have one 24 GB GPU and set this to 10, virtually you can think of it as a 34 GB GPU. Then you can load a 13B model with BF16 weight, which requires at least 26GB GPU memory. Note that this requires fast CPU-GPU interconnect, as part of the model is loaded from CPU memory to GPU memory on the fly in each model forward pass.
Default: 0
- gpu-memory-utilization** The fraction of GPU memory to be used for the model executor, which can range from 0 to 1. For example, a value of 0.5 would imply 50% GPU memory utilization. If unspecified, will use the default value of 0.9.
Default: 0.9
- num-gpu-blocks-override** If specified, ignore GPU profiling result and use this number of GPU blocks. Used for testing preemption.
- max-num-batched-tokens** Maximum number of batched tokens per iteration.
- max-num-seqs** Maximum number of sequences per iteration.
Default: 256

-
- max-logprobs** Max number of log probs to return logprobs is specified in SamplingParams.
Default: 20
 - disable-log-stats** Disable logging statistics.
Default: False
 - quantization, -q** Possible choices: aqlm, awq, deepspeedfp, tpu_int8, fp8, fbgemm_fp8, mode-lopt, marlin, gguf, gptq_marlin_24, gptq_marlin, awq_marlin, gptq, compressed-tensors, bitsandbytes, qqq, experts_int8, neuron_quant, None
Method used to quantize the weights. If None, we first check the *quantization_config* attribute in the model config file. If that is None, we assume the model weights are not quantized and use *dtype* to determine the data type of the weights.
 - rope-scaling** RoPE scaling configuration in JSON format. For example, `{"type": "dynamic", "factor": 2.0}`
 - rope-theta** RoPE theta. Use with *rope_scaling*. In some cases, changing the RoPE theta improves the performance of the scaled model.
 - enforce-eager** Always use eager-mode PyTorch. If False, will use eager mode and CUDA graph in hybrid for maximal performance and flexibility.
Default: False
 - max-context-len-to-capture** Maximum context length covered by CUDA graphs. When a sequence has context length larger than this, we fall back to eager mode. (DEPRECATED. Use `--max-seq-len-to-capture` instead)
 - max-seq-len-to-capture** Maximum sequence length covered by CUDA graphs. When a sequence has context length larger than this, we fall back to eager mode.
Default: 8192
 - disable-custom-all-reduce** See ParallelConfig.
Default: False
 - tokenizer-pool-size** Size of tokenizer pool to use for asynchronous tokenization. If 0, will use synchronous tokenization.
Default: 0
 - tokenizer-pool-type** Type of tokenizer pool to use for asynchronous tokenization. Ignored if `tokenizer_pool_size` is 0.
Default: "ray"
 - tokenizer-pool-extra-config** Extra config for tokenizer pool. This should be a JSON string that will be parsed into a dictionary. Ignored if `tokenizer_pool_size` is 0.
 - limit-mm-per-prompt** For each multimodal plugin, limit how many input instances to allow for each prompt. Expects a comma-separated list of items, e.g.: `image=16,video=2` allows a maximum of 16 images and 2 videos per prompt. Defaults to 1 for each modality.
 - enable-lora** If True, enable handling of LoRA adapters.
Default: False
 - max-loras** Max number of LoRAs in a single batch.
Default: 1

- max-lora-rank** Max LoRA rank.
Default: 16
- lora-extra-vocab-size** Maximum size of extra vocabulary that can be present in a LoRA adapter (added to the base model vocabulary).
Default: 256
- lora-dtype** Possible choices: auto, float16, bfloat16, float32
Data type for LoRA. If auto, will default to base model dtype.
Default: "auto"
- long-lora-scaling-factors** Specify multiple scaling factors (which can be different from base model scaling factor - see eg. Long LoRA) to allow for multiple LoRA adapters trained with those scaling factors to be used at the same time. If not specified, only adapters trained with the base model scaling factor are allowed.
- max-cpu-loras** Maximum number of LoRAs to store in CPU memory. Must be \geq than `max_num_seqs`. Defaults to `max_num_seqs`.
- fully-sharded-loras** By default, only half of the LoRA computation is sharded with tensor parallelism. Enabling this will use the fully sharded layers. At high sequence length, max rank or tensor parallel size, this is likely faster.
Default: False
- enable-prompt-adapter** If True, enable handling of PromptAdapters.
Default: False
- max-prompt-adapters** Max number of PromptAdapters in a batch.
Default: 1
- max-prompt-adapter-token** Max number of PromptAdapters tokens
Default: 0
- device** Possible choices: auto, cuda, neuron, cpu, openvino, tpu, xpu
Device type for vLLM execution.
Default: "auto"
- num-scheduler-steps** Maximum number of forward steps per scheduler call.
Default: 1
- scheduler-delay-factor** Apply a delay (of delay factor multiplied by previousprompt latency) before scheduling next prompt.
Default: 0.0
- enable-chunked-prefill** If set, the prefill requests can be chunked based on the `max_num_batched_tokens`.
- speculative-model** The name of the draft model to be used in speculative decoding.
- speculative-model-quantization** Possible choices: aqlm, awq, deepspeedfp, tpu_int8, fp8, fbgemm_fp8, modelopt, marlin, gguf, gptq_marlin_24, gptq_marlin, awq_marlin, gptq, compressed-tensors, bitsandbytes, qq, experts_int8, neuron_quant, None
Method used to quantize the weights of speculative model.If None, we first check the `quantization_config` attribute in the model config file. If that is None, we

assume the model weights are not quantized and use *dtype* to determine the data type of the weights.

- num-speculative-tokens** The number of speculative tokens to sample from the draft model in speculative decoding.
- speculative-draft-tensor-parallel-size, -spec-draft-tp** Number of tensor parallel replicas for the draft model in speculative decoding.
- speculative-max-model-len** The maximum sequence length supported by the draft model. Sequences over this length will skip speculation.
- speculative-disable-by-batch-size** Disable speculative decoding for new incoming requests if the number of enqueue requests is larger than this value.
- ngram-prompt-lookup-max** Max size of window for ngram prompt lookup in speculative decoding.
- ngram-prompt-lookup-min** Min size of window for ngram prompt lookup in speculative decoding.
- spec-decoding-acceptance-method** Possible choices: `rejection_sampler`, `typical_acceptance_sampler`
Specify the acceptance method to use during draft token verification in speculative decoding. Two types of acceptance routines are supported: 1) `RejectionSampler` which does not allow changing the acceptance rate of draft tokens, 2) `TypicalAcceptanceSampler` which is configurable, allowing for a higher acceptance rate at the cost of lower quality, and vice versa.
Default: “`rejection_sampler`”
- typical-acceptance-sampler-posterior-threshold** Set the lower bound threshold for the posterior probability of a token to be accepted. This threshold is used by the `TypicalAcceptanceSampler` to make sampling decisions during speculative decoding. Defaults to 0.09
- typical-acceptance-sampler-posterior-alpha** A scaling factor for the entropy-based threshold for token acceptance in the `TypicalAcceptanceSampler`. Typically defaults to $\sqrt{\text{--typical-acceptance-sampler-posterior-threshold}}$ i.e. 0.3
- disable-logprobs-during-spec-decoding** If set to `True`, token log probabilities are not returned during speculative decoding. If set to `False`, log probabilities are returned according to the settings in `SamplingParams`. If not specified, it defaults to `True`. Disabling log probabilities during speculative decoding reduces latency by skipping logprob calculation in proposal sampling, target sampling, and after accepted tokens are determined.
- model-loader-extra-config** Extra config for model loader. This will be passed to the model loader corresponding to the chosen `load_format`. This should be a JSON string that will be parsed into a dictionary.
- ignore-patterns** The pattern(s) to ignore when loading the model. Default to `'original/**/*'` to avoid repeated loading of llama’s checkpoints.
Default: []
- preemption-mode** If `'recompute'`, the engine performs preemption by recomputing; If `'swap'`, the engine performs preemption by block swapping.
- served-model-name** The model name(s) used in the API. If multiple names are provided, the server will respond to any of the provided names. The model name in the `model` field of a response will be the first name in this list. If not specified, the model name will be the same as the `--model` argument. Noted that this name(s) will also be used

in `model_name` tag content of prometheus metrics, if multiple names provided, `metricstag` will take the first one.

- qlora-adapter-name-or-path** Name or path of the QLoRA adapter.
- otlp-traces-endpoint** Target URL to which OpenTelemetry traces will be sent.
- collect-detailed-traces** Valid choices are `model`, `worker`, `all`. It makes sense to set this only if `--otlp-traces-endpoint` is set. If set, it will collect detailed traces for the specified modules. This involves use of possibly costly and or blocking operations and hence might have a performance impact.
- disable-async-output-proc** Disable async output processing. This may result in lower performance.
Default: False
- override-neuron-config** override or set neuron device configuration.
- disable-log-requests** Disable logging requests.
Default: False
- max-log-len** Max number of prompt characters or prompt ID numbers being printed in log.
Default: Unlimited

1.11.5 Tool Calling in the Chat Completion API

Named Function Calling

vLLM supports only named function calling in the chat completion API by default. It does so using Outlines, so this is enabled by default, and will work with any supported model. You are guaranteed a validly-parsable function call - not a high-quality one.

To use a named function, you need to define the functions in the `tools` parameter of the chat completion request, and specify the name of one of the tools in the `tool_choice` parameter of the chat completion request.

Config file

The `serve` module can also accept arguments from a config file in `yaml` format. The arguments in the `yaml` must be specified using the long form of the argument outlined [here](#):

For example:

```
# config.yaml
host: "127.0.0.1"
port: 6379
uvicorn-log-level: "info"
```

```
$ vllm serve SOME_MODEL --config config.yaml
```

NOTE

In case an argument is supplied using command line and the config file, the value from the commandline will take precedence. The order of priorities is `command line > config file values > defaults`.

1.11.6 Tool calling in the chat completion API

vLLM supports only named function calling in the chat completion API. The `tool_choice` options `auto` and `required` are **not yet supported** but on the roadmap.

It is the callers responsibility to prompt the model with the tool information, vLLM will not automatically manipulate the prompt.

vLLM will use guided decoding to ensure the response matches the tool parameter object defined by the JSON schema in the `tools` parameter.

Automatic Function Calling

To enable this feature, you should set the following flags:

- `--enable-auto-tool-choice` – **mandatory** Auto tool choice. tells vLLM that you want to enable the model to generate its own tool calls when it deems appropriate.
- `--tool-call-parser` – select the tool parser to use - currently either `hermes` or `mistral`. Additional tool parsers will continue to be added in the future.
- `--chat-template` – **optional** for auto tool choice. the path to the chat template which handles `tool-role` messages and `assistant-role` messages that contain previously generated tool calls. Hermes and Mistral models have tool-compatible chat templates in their `tokenizer_config.json` files, but you can specify a custom template. This argument can be set to `tool_use` if your model has a tool use-specific chat template configured in the `tokenizer_config.json`. In this case, it will be used per the `transformers` specification. More on this [here](#) from HuggingFace; and you can find an example of this in a `tokenizer_config.json` [here](#)

If your favorite tool-calling model is not supported, please feel free to contribute a parser & tool use chat template!

Hermes Models

All Nous Research Hermes-series models newer than Hermes 2 Pro should be supported.

- `NousResearch/Hermes-2-Pro-*`
- `NousResearch/Hermes-2-Theta-*`
- `NousResearch/Hermes-3-*`

*Note that the Hermes 2 **Theta** models are known to have degraded tool call quality & capabilities due to the merge step in their creation.*

Flags: `--tool-call-parser hermes`

Mistral Models

Supported models:

- `mistralai/Mistral-7B-Instruct-v0.3` (confirmed)
- Additional mistral function-calling models are compatible as well.

Known issues:

1. Mistral 7B struggles to generate parallel tool calls correctly.

2. Mistral’s `tokenizer_config.json` chat template requires tool call IDs that are exactly 9 digits, which is much shorter than what vLLM generates. Since an exception is thrown when this condition is not met, the following additional chat templates are provided:

- `examples/tool_chat_template_mistral.jinja` - this is the “official” Mistral chat template, but tweaked so that it works with vLLM’s tool call IDs (provided `tool_call_id` fields are truncated to the last 9 digits)
- `examples/tool_chat_template_mistral_parallel.jinja` - this is a “better” version that adds a tool-use system prompt when tools are provided, that results in much better reliability when working with parallel tool calling.

Recommended flags: `--tool-call-parser mistral --chat-template examples/tool_chat_template_mistral_parallel.jinja`

1.12 Deploying with Docker

vLLM offers an official Docker image for deployment. The image can be used to run OpenAI compatible server and is available on Docker Hub as `vllm/vllm-openai`.

```
$ docker run --runtime nvidia --gpus all \
  -v ~/.cache/huggingface:/root/.cache/huggingface \
  --env "HUGGING_FACE_HUB_TOKEN=<secret>" \
  -p 8000:8000 \
  --ipc=host \
  vllm/vllm-openai:latest \
  --model mistralai/Mistral-7B-v0.1
```

Note: You can either use the `ipc=host` flag or `--shm-size` flag to allow the container to access the host’s shared memory. vLLM uses PyTorch, which uses shared memory to share data between processes under the hood, particularly for tensor parallel inference.

You can build and run vLLM from source via the provided [Dockerfile](#). To build vLLM:

```
$ DOCKER_BUILDKIT=1 docker build . --target vllm-openai --tag vllm/vllm-openai #_
↳ optionally specifies: --build-arg max_jobs=8 --build-arg nvcc_threads=2
```

Note: By default vLLM will build for all GPU types for widest distribution. If you are just building for the current GPU type the machine is running on, you can add the argument `--build-arg torch_cuda_arch_list=""` for vLLM to find the current GPU type and build for that.

To run vLLM:

```
$ docker run --runtime nvidia --gpus all \
  -v ~/.cache/huggingface:/root/.cache/huggingface \
  -p 8000:8000 \
  --env "HUGGING_FACE_HUB_TOKEN=<secret>" \
  vllm/vllm-openai <args...>
```

Note: For `v0.4.1` and `v0.4.2` only - the vLLM docker images under these versions are supposed to be run under the root user since a library under the root user’s home directory, i.e. `/root/.config/vllm/nccl/cu12/libnccl.so.2.18.1` is required to be loaded during runtime. If you are running the container under a different user, you may need

to first change the permissions of the library (and all the parent directories) to allow the user to access it, then run vLLM with environment variable `VLLM_NCCL_SO_PATH=/root/.config/vllm/nccl/cu12/libnccl.so.2.18.1`.

1.13 Distributed Inference and Serving

1.13.1 How to decide the distributed inference strategy?

Before going into the details of distributed inference and serving, let's first make it clear when to use distributed inference and what are the strategies available. The common practice is:

- **Single GPU (no distributed inference):** If your model fits in a single GPU, you probably don't need to use distributed inference. Just use the single GPU to run the inference.
- **Single-Node Multi-GPU (tensor parallel inference):** If your model is too large to fit in a single GPU, but it can fit in a single node with multiple GPUs, you can use tensor parallelism. The tensor parallel size is the number of GPUs you want to use. For example, if you have 4 GPUs in a single node, you can set the tensor parallel size to 4.
- **Multi-Node Multi-GPU (tensor parallel plus pipeline parallel inference):** If your model is too large to fit in a single node, you can use tensor parallel together with pipeline parallelism. The tensor parallel size is the number of GPUs you want to use in each node, and the pipeline parallel size is the number of nodes you want to use. For example, if you have 16 GPUs in 2 nodes (8GPUs per node), you can set the tensor parallel size to 8 and the pipeline parallel size to 2.

In short, you should increase the number of GPUs and the number of nodes until you have enough GPU memory to hold the model. The tensor parallel size should be the number of GPUs in each node, and the pipeline parallel size should be the number of nodes.

After adding enough GPUs and nodes to hold the model, you can run vLLM first, which will print some logs like `# GPU blocks: 790`. Multiply the number by 16 (the block size), and you can get roughly the maximum number of tokens that can be served on the current configuration. If this number is not satisfying, e.g. you want higher throughput, you can further increase the number of GPUs or nodes, until the number of blocks is enough.

Note: There is one edge case: if the model fits in a single node with multiple GPUs, but the number of GPUs cannot divide the model size evenly, you can use pipeline parallelism, which splits the model along layers and supports uneven splits. In this case, the tensor parallel size should be 1 and the pipeline parallel size should be the number of GPUs.

1.13.2 Details for Distributed Inference and Serving

vLLM supports distributed tensor-parallel inference and serving. Currently, we support Megatron-LM's [tensor parallel algorithm](#). We also support pipeline parallel as a beta feature for online serving. We manage the distributed runtime with either [Ray](#) or python native multiprocessing. Multiprocessing can be used when deploying on a single node, multi-node inferencing currently requires Ray.

Multiprocessing will be used by default when not running in a Ray placement group and if there are sufficient GPUs available on the same node for the configured `tensor_parallel_size`, otherwise Ray will be used. This default can be overridden via the LLM class `distributed-executor-backend` argument or `--distributed-executor-backend` API server argument. Set it to `mp` for multiprocessing or `ray` for Ray. It's not required for Ray to be installed for the multiprocessing case.

To run multi-GPU inference with the LLM class, set the `tensor_parallel_size` argument to the number of GPUs you want to use. For example, to run inference on 4 GPUs:

```
from vllm import LLM
llm = LLM("facebook/opt-13b", tensor_parallel_size=4)
output = llm.generate("San Francisco is a")
```

To run multi-GPU serving, pass in the `--tensor-parallel-size` argument when starting the server. For example, to run API server on 4 GPUs:

```
$ vllm serve facebook/opt-13b \
$   --tensor-parallel-size 4
```

You can also additionally specify `--pipeline-parallel-size` to enable pipeline parallelism. For example, to run API server on 8 GPUs with pipeline parallelism and tensor parallelism:

```
$ vllm serve gpt2 \
$   --tensor-parallel-size 4 \
$   --pipeline-parallel-size 2
```

Note: Pipeline parallel is a beta feature. It is only supported for online serving as well as LLaMa, GPT2, Mixtral, Qwen, Qwen2, and Nemotron style models.

1.13.3 Multi-Node Inference and Serving

If a single node does not have enough GPUs to hold the model, you can run the model using multiple nodes. It is important to make sure the execution environment is the same on all nodes, including the model path, the Python environment. The recommended way is to use docker images to ensure the same environment, and hide the heterogeneity of the host machines via mapping them into the same docker configuration.

The first step, is to start containers and organize them into a cluster. We have provided a helper [script](#) to start the cluster.

Pick a node as the head node, and run the following command:

```
$ bash run_cluster.sh \
$   vllm/vllm-openai \
$   ip_of_head_node \
$   --head \
$   /path/to/the/huggingface/home/in/this/node
```

On the rest of the worker nodes, run the following command:

```
$ bash run_cluster.sh \
$   vllm/vllm-openai \
$   ip_of_head_node \
$   --worker \
$   /path/to/the/huggingface/home/in/this/node
```

Then you get a ray cluster of containers. Note that you need to keep the shells running these commands alive to hold the cluster. Any shell disconnect will terminate the cluster. In addition, please note that the argument `ip_of_head_node` should be the IP address of the head node, which is accessible by all the worker nodes. A common misunderstanding is to use the IP address of the worker node, which is not correct.

Then, on any node, use `docker exec -it node /bin/bash` to enter the container, execute `ray status` to check the status of the Ray cluster. You should see the right number of nodes and GPUs.

After that, on any node, you can use vLLM as usual, just as you have all the GPUs on one node. The common practice is to set the tensor parallel size to the number of GPUs in each node, and the pipeline parallel size to the number of nodes. For example, if you have 16 GPUs in 2 nodes (8GPUs per node), you can set the tensor parallel size to 8 and the pipeline parallel size to 2:

```
$ vllm serve /path/to/the/model/in/the/container \
$   --tensor-parallel-size 8 \
$   --pipeline-parallel-size 2
```

You can also use tensor parallel without pipeline parallel, just set the tensor parallel size to the number of GPUs in the cluster. For example, if you have 16 GPUs in 2 nodes (8GPUs per node), you can set the tensor parallel size to 16:

```
$ vllm serve /path/to/the/model/in/the/container \
$   --tensor-parallel-size 16
```

To make tensor parallel performant, you should make sure the communication between nodes is efficient, e.g. using high-speed network cards like Infiniband. To correctly set up the cluster to use Infiniband, append additional arguments like `--privileged -e NCCL_IB_HCA=mlx5` to the `run_cluster.sh` script. Please contact your system administrator for more information on how to set up the flags. One way to confirm if the Infiniband is working is to run vLLM with `NCCL_DEBUG=TRACE` environment variable set, e.g. `NCCL_DEBUG=TRACE vllm serve ...` and check the logs for the NCCL version and the network used. If you find `[send] via NET/Socket` in the logs, it means NCCL uses raw TCP Socket, which is not efficient for cross-node tensor parallel. If you find `[send] via NET/IB/GDRDMA` in the logs, it means NCCL uses Infiniband with GPU-Direct RDMA, which is efficient.

Warning: After you start the Ray cluster, you'd better also check the GPU-GPU communication between nodes. It can be non-trivial to set up. Please refer to the [sanity check script](#) for more information. If you need to set some environment variables for the communication configuration, you can append them to the `run_cluster.sh` script, e.g. `-e NCCL_SOCKET_IFNAME=eth0`. Note that setting environment variables in the shell (e.g. `NCCL_SOCKET_IFNAME=eth0 vllm serve ...`) only works for the processes in the same node, not for the processes in the other nodes. Setting environment variables when you create the cluster is the recommended way. See the [discussion](#) for more information.

Warning: Please make sure you downloaded the model to all the nodes (with the same path), or the model is downloaded to some distributed file system that is accessible by all nodes.

When you use huggingface repo id to refer to the model, you should append your huggingface token to the `run_cluster.sh` script, e.g. `-e HF_TOKEN=`. The recommended way is to download the model first, and then use the path to refer to the model.

1.14 Production Metrics

vLLM exposes a number of metrics that can be used to monitor the health of the system. These metrics are exposed via the `/metrics` endpoint on the vLLM OpenAI compatible API server.

The following metrics are exposed:

```
class Metrics:
    """
    vLLM uses a multiprocessing-based frontend for the OpenAI server.
    This means that we need to run prometheus_client in multiprocessing mode
```

(continues on next page)

(continued from previous page)

```

See https://prometheus.github.io/client\_python/multiprocess/ for more
details on limitations.
"""

1.15 Environment Variables

vLLM uses the following environment variables to configure the system:

Warning: Please note that `VLLM_PORT` and `VLLM_HOST_IP` set the port and ip for vLLM's **internal usage**. It is not the port and ip for the API server. If you use `--host $VLLM_HOST_IP` and `--port $VLLM_PORT` to start the API server, it will not work.

All environment variables used by vLLM are prefixed with `VLLM_`. **Special care should be taken for Kubernetes users:** please do not name the service as `vllm`, otherwise environment variables set by Kubernetes might conflict with vLLM's environment variables, because [Kubernetes sets environment variables for each service with the capitalized service name as the prefix](#).

```
environment_variables: Dict[str, Callable[[], Any]] = {

lambda:
(os.environ.get("VLLM_ALLOW_RUNTIME_LORA_UPDATING", "0").strip().lower() in
 ("1", "true")),
}
```

1.16 Usage Stats Collection

vLLM collects anonymous usage data by default to help the engineering team better understand which hardware and model configurations are widely used. This data allows them to prioritize their efforts on the most common workloads. The collected data is transparent, does not contain any sensitive information, and will be publicly released for the community's benefit.

1.16.1 What data is collected?

You can see the up to date list of data collected by vLLM in the `usage_lib.py`.

Here is an example as of v0.4.0:

```
{
  "uuid": "fbc880e9-084d-4cab-a395-8984c50f1109",
  "provider": "GCP",
  "num_cpu": 24,
  "cpu_type": "Intel(R) Xeon(R) CPU @ 2.20GHz",
  "cpu_family_model_stepping": "6,85,7",
  "total_memory": 101261135872,
  "architecture": "x86_64",
  "platform": "Linux-5.10.0-28-cloud-amd64-x86_64-with-glibc2.31",
  "gpu_count": 2,
  "gpu_type": "NVIDIA L4",
  "gpu_memory_per_device": 23580639232,
  "model_architecture": "OPTForCausalLM",
  "vllm_version": "0.3.2+cu123",
  "context": "LLM_CLASS",
  "log_time": 1711663373492490000,
  "source": "production",
  "dtype": "torch.float16",
  "tensor_parallel_size": 1,
  "block_size": 16,
  "gpu_memory_utilization": 0.9,
  "quantization": null,
  "kv_cache_dtype": "auto",
  "enable_lora": false,
  "enable_prefix_caching": false,
  "enforce_eager": false,
  "disable_custom_all_reduce": true
}
```

You can preview the collected data by running the following command:

```
tail ~/.config/vllm/usage_stats.json
```

1.16.2 Opt-out of Usage Stats Collection

You can opt-out of usage stats collection by setting the `VLLM_NO_USAGE_STATS` or `DO_NOT_TRACK` environment variable, or by creating a `~/.config/vllm/do_not_track` file:

```
# Any of the following methods can disable usage stats collection
export VLLM_NO_USAGE_STATS=1
export DO_NOT_TRACK=1
mkdir -p ~/.config/vllm && touch ~/.config/vllm/do_not_track
```

1.17 Integrations

1.17.1 Deploying and scaling up with SkyPilot

vLLM can be **run and scaled to multiple service replicas on clouds and Kubernetes** with [SkyPilot](#), an open-source framework for running LLMs on any cloud. More examples for various open models, such as Llama-3, Mixtral, etc, can be found in [SkyPilot AI gallery](#).

Prerequisites

- Go to the [HuggingFace model page](#) and request access to the model `meta-llama/Meta-Llama-3-8B-Instruct`.
- Check that you have installed SkyPilot ([docs](#)).
- Check that `sky check` shows clouds or Kubernetes are enabled.

```
pip install skypilot-nightly
sky check
```

Run on a single instance

See the vLLM SkyPilot YAML for serving, `serving.yaml`.

```
resources:
  accelerators: {L4, A10g, A10, L40, A40, A100, A100-80GB} # We can use cheaper
  ↳ accelerators for 8B model.
  use_spot: True
  disk_size: 512 # Ensure model checkpoints can fit.
  disk_tier: best
  ports: 8081 # Expose to internet traffic.

envs:
  MODEL_NAME: meta-llama/Meta-Llama-3-8B-Instruct
  HF_TOKEN: <your-huggingface-token> # Change to your own huggingface token, or use --
  ↳ env to pass.

setup: |
  conda create -n vllm python=3.10 -y
  conda activate vllm
```

(continues on next page)

(continued from previous page)

```

pip install vllm==0.4.0.post1
# Install Gradio for web UI.
pip install gradio openai
pip install flash-attn==2.5.7

run: |
conda activate vllm
echo 'Starting vllm api server...'
python -u -m vllm.entrypoints.openai.api_server \
  --port 8081 \
  --model $MODEL_NAME \
  --trust-remote-code \
  --tensor-parallel-size $SKYPILOT_NUM_GPUS_PER_NODE \
  2>&1 | tee api_server.log &

echo 'Waiting for vllm api server to start...'
while ! `cat api_server.log | grep -q 'Uvicorn running on'`; do sleep 1; done

echo 'Starting gradio server...'
git clone https://github.com/vllm-project/vllm.git || true
python vllm/examples/gradio_openai_chatbot_webserver.py \
  -m $MODEL_NAME \
  --port 8811 \
  --model-url http://localhost:8081/v1 \
  --stop-token-ids 128009,128001

```

Start the serving the Llama-3 8B model on any of the candidate GPUs listed (L4, A10g, ...):

```
HF_TOKEN="your-huggingface-token" sky launch serving.yaml --env HF_TOKEN
```

Check the output of the command. There will be a shareable gradio link (like the last line of the following). Open it in your browser to use the LLaMA model to do the text completion.

```
(task, pid=7431) Running on public URL: https://<gradio-hash>.gradio.live
```

Optional: Serve the 70B model instead of the default 8B and use more GPU:

```
HF_TOKEN="your-huggingface-token" sky launch serving.yaml --gpus A100:8 --env HF_TOKEN --
↪env MODEL_NAME=meta-llama/Meta-Llama-3-70B-Instruct
```

Scale up to multiple replicas

SkyPilot can scale up the service to multiple service replicas with built-in autoscaling, load-balancing and fault-tolerance. You can do it by adding a services section to the YAML file.

```

service:
  replicas: 2
  # An actual request for readiness probe.
  readiness_probe:
    path: /v1/chat/completions
    post_data:

```

(continues on next page)

```

model: $MODEL_NAME
messages:
  - role: user
    content: Hello! What is your name?
max_tokens: 1

```

```

service:
replicas: 2
# An actual request for readiness probe.
readiness_probe:
  path: /v1/chat/completions
  post_data:
    model: $MODEL_NAME
    messages:
      - role: user
        content: Hello! What is your name?
    max_tokens: 1

resources:
accelerators: {L4, A10g, A10, L40, A40, A100, A100-80GB} # We can use cheaper_
↪accelerators for 8B model.
use_spot: True
disk_size: 512 # Ensure model checkpoints can fit.
disk_tier: best
ports: 8081 # Expose to internet traffic.

envs:
MODEL_NAME: meta-llama/Meta-Llama-3-8B-Instruct
HF_TOKEN: <your-huggingface-token> # Change to your own huggingface token, or use --
↪env to pass.

setup: |
conda create -n vllm python=3.10 -y
conda activate vllm

pip install vllm==0.4.0.post1
# Install Gradio for web UI.
pip install gradio openai
pip install flash-attn==2.5.7

run: |
conda activate vllm
echo 'Starting vllm api server...'
python -u -m vllm.entrypoints.openai.api_server \
  --port 8081 \
  --model $MODEL_NAME \
  --trust-remote-code \
  --tensor-parallel-size $SKYPILOT_NUM_GPUS_PER_NODE \
  2>&1 | tee api_server.log

```

Start the serving the Llama-3 8B model on multiple replicas:

```
HF_TOKEN="your-huggingface-token" sky serve up -n vllm serving.yaml --env HF_TOKEN
```

Wait until the service is ready:

```
watch -n10 sky serve status vllm
```

```
Services
NAME VERSION UPTIME STATUS REPLICAS ENDPOINT
vllm 1 35s READY 2/2 xx.yy.zz.100:30001

Service Replicas
SERVICE_NAME ID VERSION IP LAUNCHED RESOURCES STATUS
↪REGION
vllm 1 1 xx.yy.zz.121 18 mins ago 1x GCP([Spot]{'L4': 1}) READY
↪us-east4
vllm 2 1 xx.yy.zz.245 18 mins ago 1x GCP([Spot]{'L4': 1}) READY
↪us-east4
```

After the service is READY, you can find a single endpoint for the service and access the service with the endpoint:

```
ENDPOINT=$(sky serve status --endpoint 8081 vllm)
curl -L http://$ENDPOINT/v1/chat/completions \
-H "Content-Type: application/json" \
-d '{
  "model": "meta-llama/Meta-Llama-3-8B-Instruct",
  "messages": [
    {
      "role": "system",
      "content": "You are a helpful assistant."
    },
    {
      "role": "user",
      "content": "Who are you?"
    }
  ],
  "stop_token_ids": [128009, 128001]
}'
```

To enable autoscaling, you could replace the *replicas* with the following configs in *service*:

```
service:
  replica_policy:
    min_replicas: 2
    max_replicas: 4
    target_qps_per_replica: 2
```

This will scale the service up to when the QPS exceeds 2 for each replica.

```
service:
  replica_policy:
    min_replicas: 2
    max_replicas: 4
    target_qps_per_replica: 2
```

(continues on next page)

```

# An actual request for readiness probe.
readiness_probe:
  path: /v1/chat/completions
  post_data:
    model: $MODEL_NAME
    messages:
      - role: user
        content: Hello! What is your name?
    max_tokens: 1

resources:
  accelerators: {L4, A10g, A10, L40, A40, A100, A100-80GB} # We can use cheaper_
↳ accelerators for 8B model.
  use_spot: True
  disk_size: 512 # Ensure model checkpoints can fit.
  disk_tier: best
  ports: 8081 # Expose to internet traffic.

envs:
  MODEL_NAME: meta-llama/Meta-Llama-3-8B-Instruct
  HF_TOKEN: <your-huggingface-token> # Change to your own huggingface token, or use --
↳ env to pass.

setup: |
conda create -n vllm python=3.10 -y
conda activate vllm

pip install vllm==0.4.0.post1
# Install Gradio for web UI.
pip install gradio openai
pip install flash-attn==2.5.7

run: |
conda activate vllm
echo 'Starting vllm api server...'
python -u -m vllm.entrypoints.openai.api_server \
  --port 8081 \
  --model $MODEL_NAME \
  --trust-remote-code \
  --tensor-parallel-size $SKYPILOT_NUM_GPUS_PER_NODE \
  2>&1 | tee api_server.log

```

To update the service with the new config:

```
HF_TOKEN="your-huggingface-token" sky serve update vllm serving.yaml --env HF_TOKEN
```

To stop the service:

```
sky serve down vllm
```

Optional: Connect a GUI to the endpoint

It is also possible to access the Llama-3 service with a separate GUI frontend, so the user requests send to the GUI will be load-balanced across replicas.

```

envs:
  MODEL_NAME: meta-llama/Meta-Llama-3-8B-Instruct
  ENDPOINT: x.x.x.x:3031 # Address of the API server running vllm.

resources:
  cpus: 2

setup: |
  conda create -n vllm python=3.10 -y
  conda activate vllm

  # Install Gradio for web UI.
  pip install gradio openai

run: |
  conda activate vllm
  export PATH=$PATH:/sbin

  echo 'Starting gradio server...'
  git clone https://github.com/vllm-project/vllm.git || true
  python vllm/examples/gradio_openai_chatbot_webserver.py \
    -m $MODEL_NAME \
    --port 8811 \
    --model-url http://$ENDPOINT/v1 \
    --stop-token-ids 128009,128001 | tee ~/gradio.log

```

1. Start the chat web UI:

```
sky launch -c gui ./gui.yaml --env ENDPOINT=$(sky serve status --endpoint vllm)
```

2. Then, we can access the GUI at the returned gradio link:

```
| INFO | stdout | Running on public URL: https://6141e84201ce0bb4ed.gradio.live
```

1.17.2 Deploying with KServe

vLLM can be deployed with [KServe](#) on Kubernetes for highly scalable distributed model serving.

Please see [this guide](#) for more details on using vLLM with KServe.

1.17.3 Deploying with NVIDIA Triton

The [Triton Inference Server](#) hosts a tutorial demonstrating how to quickly deploy a simple [facebook/opt-125m](#) model using vLLM. Please see [Deploying a vLLM model in Triton](#) for more details.

1.17.4 Deploying with BentoML

[BentoML](#) allows you to deploy a large language model (LLM) server with vLLM as the backend, which exposes OpenAI-compatible endpoints. You can serve the model locally or containerize it as an OCI-compliant image and deploy it on Kubernetes.

For details, see the tutorial [vLLM inference in the BentoML documentation](#).

1.17.5 Deploying with Cerebrum

vLLM can be run on a cloud based GPU machine with [Cerebrum](#), a serverless AI infrastructure platform that makes it easier for companies to build and deploy AI based applications.

To install the Cerebrum client, run:

```
$ pip install cerebrum
$ cerebrum login
```

Next, create your Cerebrum project, run:

```
$ cerebrum init vllm-project
```

Next, to install the required packages, add the following to your `cerebrum.toml`:

```
[cerebrum.deployment]
docker_base_image_url = "nvidia/cuda:12.1.1-runtime-ubuntu22.04"

[cerebrum.dependencies.pip]
vllm = "latest"
```

Next, let us add our code to handle inference for the LLM of your choice (*mistralai/Mistral-7B-Instruct-v0.1* for this example), add the following code to your `main.py`:

```
from vllm import LLM, SamplingParams

llm = LLM(model="mistralai/Mistral-7B-Instruct-v0.1")

def run(prompts: list[str], temperature: float = 0.8, top_p: float = 0.95):
    sampling_params = SamplingParams(temperature=temperature, top_p=top_p)
    outputs = llm.generate(prompts, sampling_params)
```

(continues on next page)

(continued from previous page)

```

# Print the outputs.
results = []
for output in outputs:
    prompt = output.prompt
    generated_text = output.outputs[0].text
    results.append({"prompt": prompt, "generated_text": generated_text})

return {"results": results}

```

Then, run the following code to deploy it to the cloud

```
$ cerebrium deploy
```

If successful, you should be returned a CURL command that you can call inference against. Just remember to end the url with the function name you are calling (in our case /run)

```

curl -X POST https://api.cortex.cerebrium.ai/v4/p-xxxxxx/vllm/run \
-H 'Content-Type: application/json' \
-H 'Authorization: <JWT TOKEN>' \
--data '{
  "prompts": [
    "Hello, my name is",
    "The president of the United States is",
    "The capital of France is",
    "The future of AI is"
  ]
}'

```

You should get a response like:

```

{
  "run_id": "52911756-3066-9ae8-bcc9-d9129d1bd262",
  "result": {
    "result": [
      {
        "prompt": "Hello, my name is",
        "generated_text": " Sarah, and I'm a teacher. I teach elementary school_
↪students. One of"
      },
      {
        "prompt": "The president of the United States is",
        "generated_text": " elected every four years. This is a democratic_
↪system.\n\n5. What"
      },
      {
        "prompt": "The capital of France is",
        "generated_text": " Paris.\n"
      },
      {
        "prompt": "The future of AI is",
        "generated_text": " bright, but it's important to approach it with a_
↪balanced and nuanced perspective."
      }
    ]
  }
}

```

(continues on next page)

```
    ],  
  },  
  "run_time_ms": 152.53663063049316  
}
```

You now have an autoscaling endpoint where you only pay for the compute you use!

1.17.6 Deploying with LWS

LeaderWorkerSet (LWS) is a Kubernetes API that aims to address common deployment patterns of AI/ML inference workloads. A major use case is for multi-host/multi-node distributed inference.

vLLM can be deployed with [LWS](#) on Kubernetes for distributed model serving.

Please see [this guide](#) for more details on deploying vLLM on Kubernetes using LWS.

1.17.7 Deploying with dstack

vLLM can be run on a cloud based GPU machine with [dstack](#), an open-source framework for running LLMs on any cloud. This tutorial assumes that you have already configured credentials, gateway, and GPU quotas on your cloud environment.

To install dstack client, run:

```
$ pip install "dstack[all]"  
$ dstack server
```

Next, to configure your dstack project, run:

```
$ mkdir -p vllm-dstack  
$ cd vllm-dstack  
$ dstack init
```

Next, to provision a VM instance with LLM of your choice (*NousResearch/Llama-2-7b-chat-hf* for this example), create the following *serve.dstack.yml* file for the dstack *Service*:

```
type: service  
  
python: "3.11"  
env:  
  - MODEL=NousResearch/Llama-2-7b-chat-hf  
port: 8000  
resources:  
  gpu: 24GB  
commands:  
  - pip install vllm  
  - vllm serve $MODEL --port 8000  
model:  
  format: openai  
  type: chat  
  name: NousResearch/Llama-2-7b-chat-hf
```

Then, run the following CLI for provisioning:

```

$ dstack run . -f serve.dstack.yml

Getting run plan...
Configuration  serve.dstack.yml
Project        deep-diver-main

Service is published at ...

```

After the provisioning, you can interact with the model by using the OpenAI SDK:

```

from openai import OpenAI

client = OpenAI(
    base_url="https://gateway.<gateway domain>",
    api_key="<YOUR-DSTACK-SERVER-ACCESS-TOKEN>"
)

completion = client.chat.completions.create(
    model="NousResearch/Llama-2-7b-chat-hf",
    messages=[
        {
            "role": "user",
            "content": "Compose a poem that explains the concept of recursion in_
↪programming.",
        }
    ]
)

print(completion.choices[0].message.content)

```

Note: dstack automatically handles authentication on the gateway using dstack's tokens. Meanwhile, if you don't want to configure a gateway, you can provision dstack *Task* instead of *Service*. The *Task* is for development purpose only. If

you want to know more about hands-on materials how to serve vLLM using dstack, check out [this repository](#)

1.17.8 Serving with Langchain

vLLM is also available via [Langchain](#) .

To install langchain, run

```
$ pip install langchain langchain_community -q
```

To run inference on a single or multiple GPUs, use VLLM class from langchain.

```
from langchain_community.llms import VLLM

llm = VLLM(model="mosaicml/mpt-7b",
           trust_remote_code=True, # mandatory for hf models
           max_new_tokens=128,
           top_k=10,
           top_p=0.95,
           temperature=0.8,
           # tensor_parallel_size=... # for distributed inference
)

print(llm("What is the capital of France ?"))
```

Please refer to this [Tutorial](#) for more details.

1.17.9 Serving with llama_index

vLLM is also available via [llama_index](#) .

To install llamaindex, run

```
$ pip install llama-index-llms-vllm -q
```

To run inference on a single or multiple GPUs, use Vllm class from llamaindex.

```
from llama_index.llms.vllm import Vllm

llm = Vllm(
    model="microsoft/Orca-2-7b",
    tensor_parallel_size=4,
    max_new_tokens=100,
    vllm_kwargs={"swap_space": 1, "gpu_memory_utilization": 0.5},
)
```

Please refer to this [Tutorial](#) for more details.

1.18 Loading Models with CoreWeave's Tensorizer

vLLM supports loading models with [CoreWeave's Tensorizer](#). vLLM model tensors that have been serialized to disk, an HTTP/HTTPS endpoint, or S3 endpoint can be deserialized at runtime extremely quickly directly to the GPU, resulting in significantly shorter Pod startup times and CPU memory usage. Tensor encryption is also supported.

For more information on CoreWeave's Tensorizer, please refer to [CoreWeave's Tensorizer documentation](#). For more information on serializing a vLLM model, as well a general usage guide to using Tensorizer with vLLM, see the [vLLM example script](#).

1.19 Frequently Asked Questions

Q: How can I serve multiple models on a single port using the OpenAI API?

A: Assuming that you're referring to using OpenAI compatible server to serve multiple models at once, that is not currently supported, you can run multiple instances of the server (each serving a different model) at the same time, and have another layer to route the incoming request to the correct server accordingly.

Q: Which model to use for offline inference embedding?

A: If you want to use an embedding model, try: <https://huggingface.co/intfloat/e5-mistral-7b-instruct>. Instead models, such as Llama-3-8b, Mistral-7B-Instruct-v0.3, are generation models rather than an embedding model

Q: Can the output of a prompt vary across runs in vLLM?

A: Yes, it can. vLLM does not guarantee stable log probabilities (logprobs) for the output tokens. Variations in logprobs may occur due to numerical instability in Torch operations or non-deterministic behavior in batched Torch operations when batching changes. For more details, see the [Numerical Accuracy section](#).

In vLLM, the same requests might be batched differently due to factors such as other concurrent requests, changes in batch size, or batch expansion in speculative decoding. These batching variations, combined with numerical instability of Torch operations, can lead to slightly different logit/logprob values at each step. Such differences can accumulate, potentially resulting in different tokens being sampled. Once a different token is sampled, further divergence is likely.

Mitigation Strategies

- For improved stability and reduced variance, use *float32*. Note that this will require more memory.
- If using *bfloat16*, switching to *float16* can also help.
- Using request seeds can aid in achieving more stable generation for temperature > 0, but discrepancies due to precision differences may still occur.

1.20 Supported Models

vLLM supports a variety of generative Transformer models in [HuggingFace Transformers](#). The following is the list of model architectures that are currently supported by vLLM. Alongside each architecture, we include some popular models that use it.

1.20.1 Decoder-only Language Models

Architecture	Models	Example HuggingFace Models	LoRA
AquilaForCausalLM	Aquila & Aquila2	BAAI/Aquila-7B, BAAI/AquilaChat-7B, etc.	
ArcticForCausalLM	Arctic	Snowflake/snowflake-arctic-base, Snowflake/snowflake-arctic-instruct, etc.	
BaiChuanForCausalLM	Baichuan & Baichuan2	baichuan-inc/Baichuan2-13B-Chat, baichuan-inc/Baichuan-7B, etc.	
BloomForCausalLM	BLOOM, BLOOMZ, BLOOMChat	bigscience/bloom, bigscience/bloomz, etc.	
ChatGLMModel	ChatGLM	THUDM/chatglm2-6b, THUDM/chatglm3-6b, etc.	
CohereForCausalLM	Command-R	CohereForAI/c4ai-command-r-v01, etc.	
DbrxForCausalLM	DBRX	databricks/dbrx-base, databricks/dbrx-instruct, etc.	
DeciLMForCausalLM	DeciLM	Deci/DeciLM-7B, Deci/DeciLM-7B-instruct, etc.	
ExaoneForCausalLM	EXAONE-3	LGAI-EXAONE/EXAONE-3.0-7.8B-Instruct, etc.	
FalconForCausalLM	Falcon	tiiuae/falcon-7b, tiiuae/falcon-40b, tiiuae/falcon-rw-7b, etc.	
GemmaForCausalLM	Gemma	google/gemma-2b, google/gemma-7b, etc.	
Gemma2ForCausalLM	Gemma2	google/gemma-2-9b, google/gemma-2-27b, etc.	
GPT2LMHeadModel	GPT-2	gpt2, gpt2-xl, etc.	
GPTBigCodeForCausalLM	StarCoder, SantaCoder, WizardCoder	bigcode/starcoder, bigcode/gpt_bigcode-santacoder, WizardLM/WizardCoder-15B-V1.0, etc.	
GPTJForCausalLM	GPT-J	EleutherAI/gpt-j-6b, nomic-ai/gpt4all-j, etc.	
GPTNeoXForCausalLM	GPT-NeoX, Pythia, OpenAssistant, Dolly V2, StableLM	EleutherAI/gpt-neox-20b, EleutherAI/pythia-12b, OpenAssistant/oasst-sft-4-pythia-12b-epoch-3.5, databricks/dolly-v2-12b, stabilityai/stablelm-tuned-alpha-7b, etc.	
InternLMForCausalLM	InternLM	internlm/internlm-7b, internlm/internlm-chat-7b, etc.	
InternLM2ForCausalLM	InternLM2	internlm/internlm2-7b, internlm/internlm2-chat-7b, etc.	
JAISLMHeadModel	Jais	core42/jais-13b, core42/jais-13b-chat, core42/jais-30b-v3, core42/jais-30b-chat-v3, etc.	
JambaForCausalLM	Jamba	ai21labs/Jamba-v0.1, etc.	
LlamaForCausalLM	Llama 3.1, Llama 3, Llama 2, LLaMA, Yi	meta-llama/Meta-Llama-3.1-405B-Instruct, meta-llama/Meta-Llama-3.1-70B, meta-llama/Meta-Llama-3-70B-Instruct, meta-llama/Llama-2-70b-hf, 01-ai/Yi-34B, etc.	
MiniCPMForCausalLM	MiniCPM	openbmb/MiniCPM-2B-sft-bf16, openbmb/MiniCPM-2B-dpo-bf16, etc.	
MistralForCausalLM	Mistral, Mistral-Instruct	mistralai/Mistral-7B-v0.1, mistralai/Mistral-7B-Instruct-v0.1, etc.	

continues on next page

Table 1 – continued from previous page

Architecture	Models	Example HuggingFace Models	LoRA
MixtralForCausalLM	Mixtral-8x7B, Mixtral-8x7B-Instruct	mistralai/Mixtral-8x7B-v0.1, mistralai/Mixtral-8x7B-Instruct-v0.1, mistral-community/Mixtral-8x22B-v0.1, etc.	
MPTForCausalLM	MPT, MPT-Instruct, MPT-Chat, MPT-StoryWriter	mosaicml/mpt-7b, mosaicml/mpt-7b-storywriter, mosaicml/mpt-30b, etc.	
NemotronForCausalLM	Nemotron-3, Nemotron-4, Minitron	nvidia/Minitron-8B-Base, mgoin/Nemotron-4-340B-Base-hf-FP8, etc.	
OLMoForCausalLM	OLMo	allenai/OLMo-1B-hf, allenai/OLMo-7B-hf, etc.	
OPTForCausalLM	OPT, OPT-IML	facebook/opt-66b, facebook/opt-impl-max-30b, etc.	
OrionForCausalLM	Orion	OrionStarAI/Orion-14B-Base, OrionStarAI/Orion-14B-Chat, etc.	
PhiForCausalLM	Phi	microsoft/phi-1.5, microsoft/phi-2, etc.	
Phi3ForCausalLM	Phi-3	microsoft/Phi-3-mini-4k-instruct, microsoft/Phi-3-mini-128k-instruct, microsoft/Phi-3-medium-128k-instruct, etc.	
Phi3SmallForCausalLM	Phi-3-Small	microsoft/Phi-3-small-8k-instruct, microsoft/Phi-3-small-128k-instruct, etc.	
PhiMoEForCausalLM	Phi-3.5-MoE	microsoft/Phi-3.5-MoE-instruct, etc.	
PersimmonForCausalLM	Persimmon	adept/persimmon-8b-base, adept/persimmon-8b-chat, etc.	
QwenLMHeadModel	Qwen	Qwen/Qwen-7B, Qwen/Qwen-7B-Chat, etc.	
Qwen2ForCausalLM	Qwen2	Qwen/Qwen2-beta-7B, Qwen/Qwen2-beta-7B-Chat, etc.	
Qwen2MoeForCausalLM	Qwen2MoE	Qwen/Qwen1.5-MoE-A2.7B, Qwen/Qwen1.5-MoE-A2.7B-Chat, etc.	
StableLmForCausalLM	StableLM	stabilityai/stablelm-3b-4e1t, stabilityai/stablelm-base-alpha-7b-v2, etc.	
StarCoder2ForCausalLM	StarCoder2	bigcode/starcoder2-3b, bigcode/starcoder2-7b, bigcode/starcoder2-15b, etc.	
XverseForCausalLM	Xverse	xverse/XVERSE-7B-Chat, xverse/XVERSE-13B-Chat, xverse/XVERSE-65B-Chat, etc.	

Note: Currently, the ROCm version of vLLM supports Mistral and Mixtral only for context lengths up to 4096.

1.20.2 Multimodal Language Models

Architecture	Models	Modalities	Example HuggingFace Models	LoRA
Blip2ForConditionalGeneration	BLIP-2	Image ^E	Salesforce/blip2-opt-2.7b, Salesforce/blip2-opt-6.7b, etc.	
ChameleonForConditionalGeneration	Chameleon	Image	facebook/chameleon-7b etc.	
FuyuForCausalLM	Fuyu	Image	adept/fuyu-8b etc.	
InternVLChatModel	InternVL2	Image ^{E+}	OpenGVLab/InternVL2-4B, OpenGVLab/InternVL2-8B, etc.	
LlavaForConditionalGeneration	LLaVA-1.5	Image ^{E+}	llava-hf/llava-1.5-7b-hf, llava-hf/llava-1.5-13b-hf, etc.	
LlavaNextForConditionalGeneration	LLaVA-NeXT	Image ^{E+}	llava-hf/llava-v1.6-mistral-7b-hf, llava-hf/llava-v1.6-vicuna-7b-hf, etc.	
LlavaNextVideoForConditionalGeneration	LLaVA-NeXT-Video	Video	llava-hf/LLaVA-NeXT-Video-7B-etc. (see note)	
MiniCPMV	MiniCPM-V	Image ⁺	openbmb/MiniCPM-V-2 (see note), openbmb/MiniCPM-Llama3-V-2_5, openbmb/MiniCPM-V-2_6, etc.	
PaliGemmaForConditionalGeneration	PaliGemma	Image ^E	google/paligemma-3b-pt-224, google/paligemma-3b-mix-224 etc.	
Phi3VForCausalLM	Phi-3-Vision, Phi-3.5-Vision	Image ^{E+}	microsoft/Phi-3-vision-128k-instruct, microsoft/Phi-3.5-vision-instruct etc.	
PixtralForConditionalGeneration	Pixtral	Image ⁺	mistralai/Pixtral-12B-2409	
QWenLMHeadModel	Qwen-VL	Image ^{E+}	Qwen/Qwen-VL, Qwen/Qwen-VL-Chat, etc.	
Qwen2VLForConditionalGeneration	Qwen2-VL (see note)	Image ⁺ / Video ⁺	Qwen/Qwen2-VL-2B-Instruct, Qwen/Qwen2-VL-7B-Instruct, Qwen/Qwen2-VL-72B-Instruct etc.	
UltravoxModel	Ultravox	Audio ^{E+}	fixie-ai/ultravox-v0_3	

vLLM

^E Pre-computed embeddings can be inputted for this modality.

+ Multiple items can be inputted per text prompt for this modality.

Note: For openbmb/MiniCPM-V-2, the official repo doesn't work yet, so we need to use a fork (Hwwh/MiniCPM-V-2) for now. For more details, please see: <https://github.com/vllm-project/vllm/pull/4087#issuecomment-2250397630>

Note: For LLaVA-NeXT-Video and Qwen2-VL, the latest release of huggingface/transformers doesn't work yet, so we need to use a developer version (21fac7abba2a37fae86106f87fcf9974fd1e3830) for now. This can be installed by running the following command:

```
pip install git+https://github.com/huggingface/transformers.  
↪git@21fac7abba2a37fae86106f87fcf9974fd1e3830
```

If your model uses one of the above model architectures, you can seamlessly run your model with vLLM. Otherwise, please refer to *Adding a New Model* and *Enabling Multimodal Inputs* for instructions on how to implement support for your model. Alternatively, you can raise an issue on our [GitHub](#) project.

Tip: The easiest way to check if your model is supported is to run the program below:

```
from vllm import LLM  
  
llm = LLM(model=...) # Name or path of your model  
output = llm.generate("Hello, my name is")  
print(output)
```

If vLLM successfully generates text, it indicates that your model is supported.

Tip: To use models from [ModelScope](#) instead of HuggingFace Hub, set an environment variable:

```
$ export VLLM_USE_MODELSCOPE=True
```

And use with `trust_remote_code=True`.

```
from vllm import LLM  
  
llm = LLM(model=..., revision=..., trust_remote_code=True) # Name or path of your model  
output = llm.generate("Hello, my name is")  
print(output)
```

1.21 Model Support Policy

At vLLM, we are committed to facilitating the integration and support of third-party models within our ecosystem. Our approach is designed to balance the need for robustness and the practical limitations of supporting a wide range of models. Here's how we manage third-party model support:

1. **Community-Driven Support:** We encourage community contributions for adding new models. When a user requests support for a new model, we welcome pull requests (PRs) from the community. These contributions are evaluated primarily on the sensibility of the output they generate, rather than strict consistency with existing implementations such as those in transformers. **Call for contribution:** PRs coming directly from model vendors are greatly appreciated!
2. **Best-Effort Consistency:** While we aim to maintain a level of consistency between the models implemented in vLLM and other frameworks like transformers, complete alignment is not always feasible. Factors like acceleration techniques and the use of low-precision computations can introduce discrepancies. Our commitment is to ensure that the implemented models are functional and produce sensible results.
3. **Issue Resolution and Model Updates:** Users are encouraged to report any bugs or issues they encounter with third-party models. Proposed fixes should be submitted via PRs, with a clear explanation of the problem and the rationale behind the proposed solution. If a fix for one model impacts another, we rely on the community to highlight and address these cross-model dependencies. Note: for bugfix PRs, it is good etiquette to inform the original author to seek their feedback.
4. **Monitoring and Updates:** Users interested in specific models should monitor the commit history for those models (e.g., by tracking changes in the `main/vllm/model_executor/models` directory). This proactive approach helps users stay informed about updates and changes that may affect the models they use.
5. **Selective Focus:** Our resources are primarily directed towards models with significant user interest and impact. Models that are less frequently used may receive less attention, and we rely on the community to play a more active role in their upkeep and improvement.

Through this approach, vLLM fosters a collaborative environment where both the core development team and the broader community contribute to the robustness and diversity of the third-party models supported in our ecosystem.

Note that, as an inference engine, vLLM does not introduce new models. Therefore, all models supported by vLLM are third-party models in this regard.

We have the following levels of testing for models:

1. **Strict Consistency:** We compare the output of the model with the output of the model in the HuggingFace Transformers library under greedy decoding. This is the most stringent test. Please refer to [models tests](#) for the models that have passed this test.
2. **Output Sensibility:** We check if the output of the model is sensible and coherent, by measuring the perplexity of the output and checking for any obvious errors. This is a less stringent test.
3. **Runtime Functionality:** We check if the model can be loaded and run without errors. This is the least stringent test. Please refer to [functionality tests](#) and [examples](#) for the models that have passed this test.
4. **Community Feedback:** We rely on the community to provide feedback on the models. If a model is broken or not working as expected, we encourage users to raise issues to report it or open pull requests to fix it. The rest of the models fall under this category.

1.22 Adding a New Model

This document provides a high-level guide on integrating a [HuggingFace Transformers](#) model into vLLM.

Note: The complexity of adding a new model depends heavily on the model’s architecture. The process is considerably straightforward if the model shares a similar architecture with an existing model in vLLM. However, for models that include new operators (e.g., a new attention mechanism), the process can be a bit more complex.

Note: By default, vLLM models do not support multi-modal inputs. To enable multi-modal support, please follow [this guide](#) after implementing the model here.

Tip: If you are encountering issues while integrating your model into vLLM, feel free to open an issue on our [GitHub](#) repository. We will be happy to help you out!

1.22.1 0. Fork the vLLM repository

Start by forking our [GitHub](#) repository and then *build it from source*. This gives you the ability to modify the codebase and test your model.

Tip: If you don’t want to fork the repository and modify vLLM’s codebase, please refer to the “Out-of-Tree Model Integration” section below.

1.22.2 1. Bring your model code

Clone the PyTorch model code from the [HuggingFace Transformers](#) repository and put it into the `vllm/model_executor/models` directory. For instance, vLLM’s [OPT model](#) was adapted from the [HuggingFace’s modeling_opt.py](#) file.

Warning: When copying the model code, make sure to review and adhere to the code’s copyright and licensing terms.

1.22.3 2. Rewrite the forward methods

Next, you need to rewrite the `forward()` method of your model by following these steps:

1. Remove any unnecessary code, such as the code only used for training.
2. Change the input parameters:

```
def forward(
    self,
    input_ids: torch.Tensor,
    - attention_mask: Optional[torch.Tensor] = None,
    - position_ids: Optional[torch.LongTensor] = None,
```

(continues on next page)

(continued from previous page)

```

-     past_key_values: Optional[List[torch.FloatTensor]] = None,
-     inputs_embeds: Optional[torch.FloatTensor] = None,
-     labels: Optional[torch.LongTensor] = None,
-     use_cache: Optional[bool] = None,
-     output_attentions: Optional[bool] = None,
-     output_hidden_states: Optional[bool] = None,
-     return_dict: Optional[bool] = None,
- ) -> Union[Tuple, CausalLMOutputWithPast]:
+     positions: torch.Tensor,
+     kv_caches: List[torch.Tensor],
+     attn_metadata: AttentionMetadata,
+ ) -> Optional[SamplerOutput]:

```

1. Update the code by considering that `input_ids` and `positions` are now flattened tensors.
2. Replace the attention operation with either `PagedAttention`, `PagedAttentionWithRoPE`, or `PagedAttentionWithALiBi` depending on the model's architecture.

Note: Currently, vLLM supports the basic multi-head attention mechanism and its variant with rotary positional embeddings. If your model employs a different attention mechanism, you will need to implement a new attention layer in vLLM.

1.22.4 3. (Optional) Implement tensor parallelism and quantization support

If your model is too large to fit into a single GPU, you can use tensor parallelism to manage it. To do this, substitute your model's linear and embedding layers with their tensor-parallel versions. For the embedding layer, you can simply replace `torch.nn.Embedding` with `VocabParallelEmbedding`. For the output LM head, you can use `ParallelLMHead`. When it comes to the linear layers, we provide the following options to parallelize them:

- `ReplicatedLinear`: Replicates the inputs and weights across multiple GPUs. No memory saving.
- `RowParallelLinear`: The input tensor is partitioned along the hidden dimension. The weight matrix is partitioned along the rows (input dimension). An *all-reduce* operation is performed after the matrix multiplication to reduce the results. Typically used for the second FFN layer and the output linear transformation of the attention layer.
- `ColumnParallelLinear`: The input tensor is replicated. The weight matrix is partitioned along the columns (output dimension). The result is partitioned along the column dimension. Typically used for the first FFN layer and the separated QKV transformation of the attention layer in the original Transformer.
- `MergedColumnParallelLinear`: Column-parallel linear that merges multiple `ColumnParallelLinear` operators. Typically used for the first FFN layer with weighted activation functions (e.g., SiLU). This class handles the sharded weight loading logic of multiple weight matrices.
- `QKVParallelLinear`: Parallel linear layer for the query, key, and value projections of the multi-head and grouped-query attention mechanisms. When number of key/value heads are less than the world size, this class replicates the key/value heads properly. This class handles the weight loading and replication of the weight matrices.

Note that all the linear layers above take `linear_method` as an input. vLLM will set this parameter according to different quantization schemes to support weight quantization.

1.22.5 4. Implement the weight loading logic

You now need to implement the `load_weights` method in your `*ForCausalLM` class. This method should load the weights from the HuggingFace's checkpoint file and assign them to the corresponding layers in your model. Specifically, for `MergedColumnParallelLinear` and `QKVParallelLinear` layers, if the original model has separated weight matrices, you need to load the different parts separately.

1.22.6 5. Register your model

Finally, register your `*ForCausalLM` class to the `_MODELS` in `vllm/model_executor/models/__init__.py`.

1.22.7 6. Out-of-Tree Model Integration

We also provide a way to integrate a model without modifying the vLLM codebase. Step 2, 3, 4 are still required, but you can skip step 1 and 5.

Just add the following lines in your code:

```
from vllm import ModelRegistry
from your_code import YourModelForCausalLM
ModelRegistry.register_model("YourModelForCausalLM", YourModelForCausalLM)
```

If you are running api server with `vllm serve <args>`, you can wrap the entrypoint with the following code:

```
from vllm import ModelRegistry
from your_code import YourModelForCausalLM
ModelRegistry.register_model("YourModelForCausalLM", YourModelForCausalLM)
import runpy
runpy.run_module('vllm.entrypoints.openai.api_server', run_name='__main__')
```

Save the above code in a file and run it with `python your_file.py <args>`.

1.23 Enabling Multimodal Inputs

This document walks you through the steps to extend a vLLM model so that it accepts *multi-modal* inputs.

See also:

Adding a New Model

1.23.1 1. Update the base vLLM model

It is assumed that you have already implemented the model in vLLM according to *these steps*. Further update the model as follows:

- Implement the `SupportsMultiModal` interface.

```
+ from vllm.model_executor.models.interfaces import SupportsMultiModal
- class YourModelForImage2Seq(nn.Module):
+ class YourModelForImage2Seq(nn.Module, SupportsMultiModal):
```

Note: The model class does not have to be named `*ForCausalLM`. Check out [the HuggingFace Transformers documentation](#) for some examples.

- If you haven't already done so, reserve a keyword parameter in `forward()` for each input tensor that corresponds to a multi-modal input, as shown in the following example:

```
def forward(
    self,
    input_ids: torch.Tensor,
    positions: torch.Tensor,
    kv_caches: List[torch.Tensor],
    attn_metadata: AttentionMetadata,
+   pixel_values: torch.Tensor,
) -> SamplerOutput:
```

1.23.2 2. Register input mappers

For each modality type that the model accepts as input, decorate the model class with `MULTIMODAL_REGISTRY.register_input_mapper`. This decorator accepts a function that maps multi-modal inputs to the keyword arguments you have previously defined in `forward()`.

```
from vllm.model_executor.models.interfaces import SupportsMultiModal
+ from vllm.multimodal import MULTIMODAL_REGISTRY

+ @MULTIMODAL_REGISTRY.register_image_input_mapper()
class YourModelForImage2Seq(nn.Module, SupportsMultiModal):
```

A default mapper is available for each modality in the core vLLM library. This input mapper will be used if you do not provide your own function.

See also:

Input Processing Pipeline

1.23.3 3. Register maximum number of multi-modal tokens

For each modality type that the model accepts as input, calculate the maximum possible number of tokens per data instance and register it via `INPUT_REGISTRY.register_dummy_data`.

```
from vllm.inputs import INPUT_REGISTRY
from vllm.model_executor.models.interfaces import SupportsMultiModal
from vllm.multimodal import MULTIMODAL_REGISTRY

@MULTIMODAL_REGISTRY.register_image_input_mapper()
+ @MULTIMODAL_REGISTRY.register_max_image_tokens(<your_calculation>)
@INPUT_REGISTRY.register_dummy_data(<your_dummy_data_factory>)
class YourModelForImage2Seq(nn.Module, SupportsMultiModal):
```

Here are some examples:

- Image inputs (static feature size): [LLaVA-1.5 Model](#)
- Image inputs (dynamic feature size): [LLaVA-NeXT Model](#)

See also:

Input Processing Pipeline

1.23.4 4. (Optional) Register dummy data

During startup, dummy data is passed to the vLLM model to allocate memory. This only consists of text input by default, which may not be applicable to multi-modal models. In such cases, you can define your own dummy data by registering a factory method via `INPUT_REGISTRY.register_dummy_data`.

```

from vllm.inputs import INPUT_REGISTRY
from vllm.model_executor.models.interfaces import SupportsMultiModal
from vllm.multimodal import MULTIMODAL_REGISTRY

@MULTIMODAL_REGISTRY.register_image_input_mapper()
@MULTIMODAL_REGISTRY.register_max_image_tokens(<your_calculation>)
+ @INPUT_REGISTRY.register_dummy_data(<your_dummy_data_factory>)
class YourModelForImage2Seq(nn.Module, SupportsMultiModal):

```

Note: The dummy data should have the maximum possible number of multi-modal tokens, as described in the previous step.

Here are some examples:

- Image inputs (static feature size): [LLaVA-1.5 Model](#)
- Image inputs (dynamic feature size): [LLaVA-NeXT Model](#)

See also:

Input Processing Pipeline

1.23.5 5. (Optional) Register input processor

Sometimes, there is a need to process inputs at the `LLMEngine` level before they are passed to the model executor. This is often due to the fact that unlike implementations in HuggingFace Transformers, the reshaping and/or expansion of multi-modal embeddings needs to take place outside model's `forward()` call. You can register input processors via `INPUT_REGISTRY.register_input_processor`.

```

from vllm.inputs import INPUT_REGISTRY
from vllm.model_executor.models.interfaces import SupportsMultiModal
from vllm.multimodal import MULTIMODAL_REGISTRY

@MULTIMODAL_REGISTRY.register_image_input_mapper()
@MULTIMODAL_REGISTRY.register_max_image_tokens(<your_calculation>)
@INPUT_REGISTRY.register_dummy_data(<your_dummy_data_factory>)
+ @INPUT_REGISTRY.register_input_processor(<your_input_processor>)
class YourModelForImage2Seq(nn.Module, SupportsMultiModal):

```

A common use case of input processors is inserting placeholder tokens to leverage the vLLM framework for attention mask generation. Here are some examples:

- Insert static number of image tokens: [LLaVA-1.5 Model](#)
- Insert dynamic number of image tokens: [LLaVA-NeXT Model](#)

1.24.1 Named Arguments

--model	Name or path of the huggingface model to use. Default: “facebook/opt-125m”
--tokenizer	Name or path of the huggingface tokenizer to use. If unspecified, model name or path will be used.
--skip-tokenizer-init	Skip initialization of tokenizer and detokenizer
--revision	The specific model version to use. It can be a branch name, a tag name, or a commit id. If unspecified, will use the default version.
--code-revision	The specific revision to use for the model code on Hugging Face Hub. It can be a branch name, a tag name, or a commit id. If unspecified, will use the default version.

-
- tokenizer-revision** Revision of the huggingface tokenizer to use. It can be a branch name, a tag name, or a commit id. If unspecified, will use the default version.
- tokenizer-mode** Possible choices: auto, slow, mistral
The tokenizer mode.
- “auto” will use the fast tokenizer if available.
 - “slow” will always use the slow tokenizer.
 - “mistral” will always use the *mistral_common* tokenizer.
- Default: “auto”
- trust-remote-code** Trust remote code from huggingface.
- download-dir** Directory to download and load the weights, default to the default cache dir of huggingface.
- load-format** Possible choices: auto, pt, safetensors, npcache, dummy, tensorizer, sharded_state, gguf, bitsandbytes, mistral
The format of the model weights to load.
- “auto” will try to load the weights in the safetensors format and fall back to the pytorch bin format if safetensors format is not available.
 - “pt” will load the weights in the pytorch bin format.
 - “safetensors” will load the weights in the safetensors format.
 - “npcache” will load the weights in pytorch format and store a numpy cache to speed up the loading.
 - “dummy” will initialize the weights with random values, which is mainly for profiling.
 - “tensorizer” will load the weights using tensorizer from CoreWeave. See the Tensorize vLLM Model script in the Examples section for more information.
 - “bitsandbytes” will load the weights using bitsandbytes quantization.
- Default: “auto”
- config-format** Possible choices: auto, hf, mistral
The format of the model config to load.
- “auto” will try to load the config in hf format if available else it will try to load in mistral format
- Default: “auto”
- dtype** Possible choices: auto, half, float16, bfloat16, float, float32
Data type for model weights and activations.
- “auto” will use FP16 precision for FP32 and FP16 models, and BF16 precision for BF16 models.
 - “half” for FP16. Recommended for AWQ quantization.
 - “float16” is the same as “half”.
 - “bfloat16” for a balance between precision and range.
 - “float” is shorthand for FP32 precision.

- “float32” for FP32 precision.
- Default: “auto”
- kv-cache-dtype** Possible choices: auto, fp8, fp8_e5m2, fp8_e4m3
- Data type for kv cache storage. If “auto”, will use model data type. CUDA 11.8+ supports fp8 (=fp8_e4m3) and fp8_e5m2. ROCm (AMD GPU) supports fp8 (=fp8_e4m3)
- Default: “auto”
- quantization-param-path** Path to the JSON file containing the KV cache scaling factors. This should generally be supplied, when KV cache dtype is FP8. Otherwise, KV cache scaling factors default to 1.0, which may cause accuracy issues. FP8_E5M2 (without scaling) is only supported on cuda version greater than 11.8. On ROCm (AMD GPU), FP8_E4M3 is instead supported for common inference criteria.
- max-model-len** Model context length. If unspecified, will be automatically derived from the model config.
- guided-decoding-backend** Possible choices: outlines, lm-format-enforcer
- Which engine will be used for guided decoding (JSON schema / regex etc) by default. Currently support <https://github.com/outlines-dev/outlines> and <https://github.com/noamgat/lm-format-enforcer>. Can be overridden per request via `guided_decoding_backend` parameter.
- Default: “outlines”
- distributed-executor-backend** Possible choices: ray, mp
- Backend to use for distributed serving. When more than 1 GPU is used, will be automatically set to “ray” if installed or “mp” (multiprocessing) otherwise.
- worker-use-ray** Deprecated, use `--distributed-executor-backend=ray`.
- pipeline-parallel-size, -pp** Number of pipeline stages.
- Default: 1
- tensor-parallel-size, -tp** Number of tensor parallel replicas.
- Default: 1
- max-parallel-loading-workers** Load model sequentially in multiple batches, to avoid RAM OOM when using tensor parallel and large models.
- ray-workers-use-nsight** If specified, use nsight to profile Ray workers.
- block-size** Possible choices: 8, 16, 32
- Token block size for contiguous chunks of tokens. This is ignored on neuron devices and set to `max-model-len`
- Default: 16
- enable-prefix-caching** Enables automatic prefix caching.
- disable-sliding-window** Disables sliding window, capping to sliding window size
- use-v2-block-manager** Use BlockSpaceMangerV2.
- num-lookahead-slots** Experimental scheduling config necessary for speculative decoding. This will be replaced by speculative config in the future; it is present to enable correctness tests until then.

- Default: 0
- seed** Random seed for operations.
- Default: 0
- swap-space** CPU swap space size (GiB) per GPU.
- Default: 4
- cpu-offload-gb** The space in GiB to offload to CPU, per GPU. Default is 0, which means no offloading. Intuitively, this argument can be seen as a virtual way to increase the GPU memory size. For example, if you have one 24 GB GPU and set this to 10, virtually you can think of it as a 34 GB GPU. Then you can load a 13B model with BF16 weight, which requires at least 26GB GPU memory. Note that this requires fast CPU-GPU interconnect, as part of the model is loaded from CPU memory to GPU memory on the fly in each model forward pass.
- Default: 0
- gpu-memory-utilization** The fraction of GPU memory to be used for the model executor, which can range from 0 to 1. For example, a value of 0.5 would imply 50% GPU memory utilization. If unspecified, will use the default value of 0.9.
- Default: 0.9
- num-gpu-blocks-override** If specified, ignore GPU profiling result and use this number of GPU blocks. Used for testing preemption.
- max-num-batched-tokens** Maximum number of batched tokens per iteration.
- max-num-seqs** Maximum number of sequences per iteration.
- Default: 256
- max-logprobs** Max number of log probs to return logprobs is specified in SamplingParams.
- Default: 20
- disable-log-stats** Disable logging statistics.
- quantization, -q** Possible choices: aqlm, awq, deepspeedfp, tpu_int8, fp8, fbgemm_fp8, mode-lopt, marlin, gguf, gptq_marlin_24, gptq_marlin, awq_marlin, gptq, compressed-tensors, bitsandbytes, qqq, experts_int8, neuron_quant, None
- Method used to quantize the weights. If None, we first check the *quantization_config* attribute in the model config file. If that is None, we assume the model weights are not quantized and use *dtype* to determine the data type of the weights.
- rope-scaling** RoPE scaling configuration in JSON format. For example, `{"type": "dynamic", "factor": 2.0}`
- rope-theta** RoPE theta. Use with *rope_scaling*. In some cases, changing the RoPE theta improves the performance of the scaled model.
- enforce-eager** Always use eager-mode PyTorch. If False, will use eager mode and CUDA graph in hybrid for maximal performance and flexibility.
- max-context-len-to-capture** Maximum context length covered by CUDA graphs. When a sequence has context length larger than this, we fall back to eager mode. (DEPRECATED. Use `--max-seq-len-to-capture` instead)
- max-seq-len-to-capture** Maximum sequence length covered by CUDA graphs. When a sequence has context length larger than this, we fall back to eager mode.

- Default: 8192
- disable-custom-all-reduce** See ParallelConfig.
- tokenizer-pool-size** Size of tokenizer pool to use for asynchronous tokenization. If 0, will use synchronous tokenization.
- Default: 0
- tokenizer-pool-type** Type of tokenizer pool to use for asynchronous tokenization. Ignored if `tokenizer_pool_size` is 0.
- Default: "ray"
- tokenizer-pool-extra-config** Extra config for tokenizer pool. This should be a JSON string that will be parsed into a dictionary. Ignored if `tokenizer_pool_size` is 0.
- limit-mm-per-prompt** For each multimodal plugin, limit how many input instances to allow for each prompt. Expects a comma-separated list of items, e.g.: `image=16,video=2` allows a maximum of 16 images and 2 videos per prompt. Defaults to 1 for each modality.
- enable-lora** If True, enable handling of LoRA adapters.
- max-loras** Max number of LoRAs in a single batch.
- Default: 1
- max-lora-rank** Max LoRA rank.
- Default: 16
- lora-extra-vocab-size** Maximum size of extra vocabulary that can be present in a LoRA adapter (added to the base model vocabulary).
- Default: 256
- lora-dtype** Possible choices: auto, float16, bfloat16, float32
- Data type for LoRA. If auto, will default to base model dtype.
- Default: "auto"
- long-lora-scaling-factors** Specify multiple scaling factors (which can be different from base model scaling factor - see eg. Long LoRA) to allow for multiple LoRA adapters trained with those scaling factors to be used at the same time. If not specified, only adapters trained with the base model scaling factor are allowed.
- max-cpu-loras** Maximum number of LoRAs to store in CPU memory. Must be \geq than `max_num_seqs`. Defaults to `max_num_seqs`.
- fully-sharded-loras** By default, only half of the LoRA computation is sharded with tensor parallelism. Enabling this will use the fully sharded layers. At high sequence length, max rank or tensor parallel size, this is likely faster.
- enable-prompt-adapter** If True, enable handling of PromptAdapters.
- max-prompt-adapters** Max number of PromptAdapters in a batch.
- Default: 1
- max-prompt-adapter-token** Max number of PromptAdapters tokens
- Default: 0
- device** Possible choices: auto, cuda, neuron, cpu, openvino, tpu, xpu
- Device type for vLLM execution.

Default: “auto”

--num-scheduler-steps Maximum number of forward steps per scheduler call.

Default: 1

--scheduler-delay-factor Apply a delay (of delay factor multiplied by previous prompt latency) before scheduling next prompt.

Default: 0.0

--enable-chunked-prefill If set, the prefill requests can be chunked based on the `max_num_batched_tokens`.

--speculative-model The name of the draft model to be used in speculative decoding.

--speculative-model-quantization Possible choices: `aqlm`, `awq`, `deepspeedfp`, `tpu_int8`, `fp8`, `fbgemm_fp8`, `modelopt`, `marlin`, `gguf`, `gptq_marlin_24`, `gptq_marlin`, `awq_marlin`, `gptq`, `compressed-tensors`, `bitsandbytes`, `qqq`, `experts_int8`, `neuron_quant`, `None`

Method used to quantize the weights of speculative model. If `None`, we first check the `quantization_config` attribute in the model config file. If that is `None`, we assume the model weights are not quantized and use `dtype` to determine the data type of the weights.

--num-speculative-tokens The number of speculative tokens to sample from the draft model in speculative decoding.

--speculative-draft-tensor-parallel-size, --spec-draft-tp Number of tensor parallel replicas for the draft model in speculative decoding.

--speculative-max-model-len The maximum sequence length supported by the draft model. Sequences over this length will skip speculation.

--speculative-disable-by-batch-size Disable speculative decoding for new incoming requests if the number of enqueue requests is larger than this value.

--ngram-prompt-lookup-max Max size of window for ngram prompt lookup in speculative decoding.

--ngram-prompt-lookup-min Min size of window for ngram prompt lookup in speculative decoding.

--spec-decoding-acceptance-method Possible choices: `rejection_sampler`, `typical_acceptance_sampler`

Specify the acceptance method to use during draft token verification in speculative decoding. Two types of acceptance routines are supported: 1) `RejectionSampler` which does not allow changing the acceptance rate of draft tokens, 2) `TypicalAcceptanceSampler` which is configurable, allowing for a higher acceptance rate at the cost of lower quality, and vice versa.

Default: “rejection_sampler”

--typical-acceptance-sampler-posterior-threshold Set the lower bound threshold for the posterior probability of a token to be accepted. This threshold is used by the `TypicalAcceptanceSampler` to make sampling decisions during speculative decoding. Defaults to 0.09

--typical-acceptance-sampler-posterior-alpha A scaling factor for the entropy-based threshold for token acceptance in the `TypicalAcceptanceSampler`. Typically defaults to `sqrt(-typical-acceptance-sampler-posterior-threshold)` i.e. 0.3

--disable-logprobs-during-spec-decoding If set to `True`, token log probabilities are not returned during speculative decoding. If set to `False`, log probabilities are returned according to the settings in `SamplingParams`. If not specified, it defaults to `True`. Disabling

log probabilities during speculative decoding reduces latency by skipping logprob calculation in proposal sampling, target sampling, and after accepted tokens are determined.

- model-loader-extra-config** Extra config for model loader. This will be passed to the model loader corresponding to the chosen `load_format`. This should be a JSON string that will be parsed into a dictionary.
- ignore-patterns** The pattern(s) to ignore when loading the model. Default to `'original/**/*'` to avoid repeated loading of llama's checkpoints.
Default: []
- preemption-mode** If `'recompute'`, the engine performs preemption by recomputing; If `'swap'`, the engine performs preemption by block swapping.
- served-model-name** The model name(s) used in the API. If multiple names are provided, the server will respond to any of the provided names. The model name in the `model` field of a response will be the first name in this list. If not specified, the model name will be the same as the `-model` argument. Noted that this name(s) will also be used in `model_name` tag content of prometheus metrics, if multiple names provided, `metricstag` will take the first one.
- qlora-adapter-name-or-path** Name or path of the QLoRA adapter.
- otlp-traces-endpoint** Target URL to which OpenTelemetry traces will be sent.
- collect-detailed-traces** Valid choices are `model,worker,all`. It makes sense to set this only if `--otlp-traces-endpoint` is set. If set, it will collect detailed traces for the specified modules. This involves use of possibly costly and or blocking operations and hence might have a performance impact.
- disable-async-output-proc** Disable async output processing. This may result in lower performance.
- override-neuron-config** override or set neuron device configuration.

1.24.2 Async Engine Arguments

Below are the additional arguments related to the asynchronous engine:

```
usage: vllm serve [-h] [--disable-log-requests]
```

Named Arguments

- disable-log-requests** Disable logging requests.

1.25 Using LoRA adapters

This document shows you how to use [LoRA adapters](#) with vLLM on top of a base model.

LoRA adapters can be used with any vLLM model that implements `SupportsLoRA`.

Adapters can be efficiently served on a per request basis with minimal overhead. First we download the adapter(s) and save them locally with

```
from huggingface_hub import snapshot_download

sql_lora_path = snapshot_download(repo_id="yard1/llama-2-7b-sql-lora-test")
```

Then we instantiate the base model and pass in the `enable_lora=True` flag:

```
from vllm import LLM, SamplingParams
from vllm.lora.request import LoRARequest

llm = LLM(model="meta-llama/Llama-2-7b-hf", enable_lora=True)
```

We can now submit the prompts and call `llm.generate` with the `lora_request` parameter. The first parameter of `LoRARequest` is a human identifiable name, the second parameter is a globally unique ID for the adapter and the third parameter is the path to the LoRA adapter.

```
sampling_params = SamplingParams(
    temperature=0,
    max_tokens=256,
    stop=["[/assistant]"]
)

prompts = [
    "[user] Write a SQL query to answer the question based on the table schema.\n\n",
    "↪context: CREATE TABLE table_name_74 (icao VARCHAR, airport VARCHAR)\n\n question: Name",
    "↪the ICAO for lilongwe international airport [/user] [assistant]",
    "[user] Write a SQL query to answer the question based on the table schema.\n\n",
    "↪context: CREATE TABLE table_name_11 (nationality VARCHAR, elector VARCHAR)\n\n",
    "↪question: When Anchero Pantaleone was the elector what is under nationality? [/user]",
    "↪[assistant]",
]

outputs = llm.generate(
    prompts,
    sampling_params,
    lora_request=LoRARequest("sql_adapter", 1, sql_lora_path)
)
```

Check out [examples/multilora_inference.py](#) for an example of how to use LoRA adapters with the async engine and how to use more advanced configuration options.

1.25.1 Serving LoRA Adapters

LoRA adapted models can also be served with the Open-AI compatible vLLM server. To do so, we use `--lora-modules {name}={path} {name}={path}` to specify each LoRA module when we kickoff the server:

```
vllm serve meta-llama/Llama-2-7b-hf \
  --enable-lora \
  --lora-modules sql-lora=$HOME/.cache/huggingface/hub/models--yard1--llama-2-7b-sql-
  ↪lora-test/snapshots/0dfa347e8877a4d4ed19ee56c140fa518470028c/
```

Note: The commit ID `0dfa347e8877a4d4ed19ee56c140fa518470028c` may change over time. Please check the latest

commit ID in your environment to ensure you are using the correct one.

The server endpoint accepts all other LoRA configuration parameters (`max_loras`, `max_lora_rank`, `max_cpu_loras`, etc.), which will apply to all forthcoming requests. Upon querying the `/models` endpoint, we should see our LoRA along with its base model:

```
curl localhost:8000/v1/models | jq .
{
  "object": "list",
  "data": [
    {
      "id": "meta-llama/Llama-2-7b-hf",
      "object": "model",
      ...
    },
    {
      "id": "sql-lora",
      "object": "model",
      ...
    }
  ]
}
```

Requests can specify the LoRA adapter as if it were any other model via the `model` request parameter. The requests will be processed according to the server-wide LoRA configuration (i.e. in parallel with base model requests, and potentially other LoRA adapter requests if they were provided and `max_loras` is set high enough).

The following is an example request

```
curl http://localhost:8000/v1/completions \
  -H "Content-Type: application/json" \
  -d '{
    "model": "sql-lora",
    "prompt": "San Francisco is a",
    "max_tokens": 7,
    "temperature": 0
  }' | jq
```

1.25.2 Dynamically serving LoRA Adapters

In addition to serving LoRA adapters at server startup, the vLLM server now supports dynamically loading and unloading LoRA adapters at runtime through dedicated API endpoints. This feature can be particularly useful when the flexibility to change models on-the-fly is needed.

Note: Enabling this feature in production environments is risky as user may participate model adapter management.

To enable dynamic LoRA loading and unloading, ensure that the environment variable `VLLM_ALLOW_RUNTIME_LORA_UPDATING` is set to `True`. When this option is enabled, the API server will log a warning to indicate that dynamic loading is active.

```
export VLLM_ALLOW_RUNTIME_LORA_UPDATING=True
```

Loading a LoRA Adapter:

To dynamically load a LoRA adapter, send a POST request to the `/v1/load_lora_adapter` endpoint with the necessary details of the adapter to be loaded. The request payload should include the name and path to the LoRA adapter.

Example request to load a LoRA adapter:

```
curl -X POST http://localhost:8000/v1/load_lora_adapter \
-H "Content-Type: application/json" \
-d '{
  "lora_name": "sql_adapter",
  "lora_path": "/path/to/sql-lora-adapter"
}'
```

Upon a successful request, the API will respond with a 200 OK status code. If an error occurs, such as if the adapter cannot be found or loaded, an appropriate error message will be returned.

Unloading a LoRA Adapter:

To unload a LoRA adapter that has been previously loaded, send a POST request to the `/v1/unload_lora_adapter` endpoint with the name or ID of the adapter to be unloaded.

Example request to unload a LoRA adapter:

```
curl -X POST http://localhost:8000/v1/unload_lora_adapter \
-H "Content-Type: application/json" \
-d '{
  "lora_name": "sql_adapter"
}'
```

1.26 Using VLMs

vLLM provides experimental support for Vision Language Models (VLMs). See the [list of supported VLMs here](#). This document shows you how to run and serve these models using vLLM.

Important: We are actively iterating on VLM support. Expect breaking changes to VLM usage and development in upcoming releases without prior deprecation.

We are continuously improving user & developer experience for VLMs. Please [open an issue on GitHub](#) if you have any feedback or feature requests.

1.26.1 Offline Inference

Single-image input

The `LLM` class can be instantiated in much the same way as language-only models.

```
llm = LLM(model="llava-hf/llava-1.5-7b-hf")
```

Note: We have removed all vision language related CLI args in the 0.5.1 release. **This is a breaking change**, so please update your code to follow the above snippet. Specifically, `image_feature_size` can no longer be specified as we now calculate that internally for each model.

To pass an image to the model, note the following in `vllm.inputs.PromptInputs`:

- `prompt`: The prompt should follow the format that is documented on HuggingFace.
- `multi_modal_data`: This is a dictionary that follows the schema defined in `vllm.multimodal.MultiModalDataDict`.

```
# Refer to the HuggingFace repo for the correct format to use
prompt = "USER: <image>\nWhat is the content of this image?\nASSISTANT:"

# Load the image using PIL.Image
image = PIL.Image.open(...)

# Single prompt inference
outputs = llm.generate({
    "prompt": prompt,
    "multi_modal_data": {"image": image},
})

for o in outputs:
    generated_text = o.outputs[0].text
    print(generated_text)

# Inference with image embeddings as input
image_embeds = torch.load(...) # torch.Tensor of shape (1, image_feature_size, hidden_
    ↪ size of LM)
outputs = llm.generate({
    "prompt": prompt,
    "multi_modal_data": {"image": image_embeds},
})

for o in outputs:
    generated_text = o.outputs[0].text
    print(generated_text)

# Batch inference
image_1 = PIL.Image.open(...)
image_2 = PIL.Image.open(...)
outputs = llm.generate(
    [
        {
            "prompt": "USER: <image>\nWhat is the content of this image?\nASSISTANT:",
            "multi_modal_data": {"image": image_1},
        },
        {
            "prompt": "USER: <image>\nWhat's the color of this image?\nASSISTANT:",
            "multi_modal_data": {"image": image_2},
        }
    ]
)

for o in outputs:
    generated_text = o.outputs[0].text
    print(generated_text)
```

A code example can be found in `examples/offline_inference_vision_language.py`.

Multi-image input

Multi-image input is only supported for a subset of VLMs, as shown *here*.

To enable multiple multi-modal items per text prompt, you have to set `limit_mm_per_prompt` for the `LLM` class.

```
llm = LLM(
    model="microsoft/Phi-3.5-vision-instruct",
    trust_remote_code=True, # Required to load Phi-3.5-vision
    max_model_len=4096, # Otherwise, it may not fit in smaller GPUs
    limit_mm_per_prompt={"image": 2}, # The maximum number to accept
)
```

Instead of passing in a single image, you can pass in a list of images.

```
# Refer to the HuggingFace repo for the correct format to use
prompt = "<|user|>\n<image_1>\n<image_2>\nWhat is the content of each image?<|end|>\n\n\n-><|assistant|>\n"

# Load the images using PIL.Image
image1 = PIL.Image.open(...)
image2 = PIL.Image.open(...)

outputs = llm.generate({
    "prompt": prompt,
    "multi_modal_data": {
        "image": [image1, image2]
    },
})

for o in outputs:
    generated_text = o.outputs[0].text
    print(generated_text)
```

A code example can be found in `examples/offline_inference_vision_language_multi_image.py`.

1.26.2 Online Inference

OpenAI Vision API

You can serve vision language models with vLLM's HTTP server that is compatible with OpenAI Vision API.

Below is an example on how to launch the same `microsoft/Phi-3.5-vision-instruct` with vLLM's OpenAI-compatible API server.

```
vllm serve microsoft/Phi-3.5-vision-instruct --max-model-len 4096 \
  --trust-remote-code --limit-mm-per-prompt image=2
```

Important: Since OpenAI Vision API is based on Chat Completions API, a chat template is **required** to launch the API server.

Although Phi-3.5-Vision comes with a chat template, for other models you may have to provide one if the model's tokenizer does not come with it. The chat template can be inferred based on the documentation on the model's HuggingFace repo. For example, LLaVA-1.5 (llava-hf/llava-1.5-7b-hf) requires a chat template that can be found [here](#).

To consume the server, you can use the OpenAI client like in the example below:

```
from openai import OpenAI

openai_api_key = "EMPTY"
openai_api_base = "http://localhost:8000/v1"

client = OpenAI(
    api_key=openai_api_key,
    base_url=openai_api_base,
)

# Single-image input inference
image_url = "https://upload.wikimedia.org/wikipedia/commons/thumb/d/dd/Gfp-wisconsin-
↳madison-the-nature-boardwalk.jpg/2560px-Gfp-wisconsin-madison-the-nature-boardwalk.jpg"

chat_response = client.chat.completions.create(
    model="microsoft/Phi-3.5-vision-instruct",
    messages=[{
        "role": "user",
        "content": [
            # NOTE: The prompt formatting with the image token `` is not needed
            # since the prompt will be processed automatically by the API server.
            {"type": "text", "text": "What's in this image?"},
            {"type": "image_url", "image_url": {"url": image_url}},
        ],
    }],
)
print("Chat completion output:", chat_response.choices[0].message.content)

# Multi-image input inference
image_url_duck = "https://upload.wikimedia.org/wikipedia/commons/d/da/2015_Kaczka_krzy%C5
↳%BCowka_w_wodzie_%28samiec%29.jpg"
image_url_lion = "https://upload.wikimedia.org/wikipedia/commons/7/77/002_The_lion_king_
↳Snyggve_in_the_Serengeti_National_Park_Photo_by_Giles_Laurent.jpg"

chat_response = client.chat.completions.create(
    model="microsoft/Phi-3.5-vision-instruct",
    messages=[{
        "role": "user",
        "content": [
            {"type": "text", "text": "What are the animals in these images?"},
            {"type": "image_url", "image_url": {"url": image_url_duck}},
            {"type": "image_url", "image_url": {"url": image_url_lion}},
        ],
    }],
)
print("Chat completion output:", chat_response.choices[0].message.content)
```

A full code example can be found in [examples/openai_vision_api_client.py](#).

Note: By default, the timeout for fetching images through http url is 5 seconds. You can override this by setting the environment variable:

```
export VLLM_IMAGE_FETCH_TIMEOUT=<timeout>
```

Note: There is no need to format the prompt in the API request since it will be handled by the server.

1.27 Speculative decoding in vLLM

Warning: Please note that speculative decoding in vLLM is not yet optimized and does not usually yield inter-token latency reductions for all prompt datasets or sampling parameters. The work to optimize it is ongoing and can be followed in [this issue](#).

This document shows how to use [Speculative Decoding](#) with vLLM. Speculative decoding is a technique which improves inter-token latency in memory-bound LLM inference.

1.27.1 Speculating with a draft model

The following code configures vLLM in an offline mode to use speculative decoding with a draft model, speculating 5 tokens at a time.

```
from vllm import LLM, SamplingParams

prompts = [
    "The future of AI is",
]
sampling_params = SamplingParams(temperature=0.8, top_p=0.95)

llm = LLM(
    model="facebook/opt-6.7b",
    tensor_parallel_size=1,
    speculative_model="facebook/opt-125m",
    num_speculative_tokens=5,
    use_v2_block_manager=True,
)
outputs = llm.generate(prompts, sampling_params)

for output in outputs:
    prompt = output.prompt
    generated_text = output.outputs[0].text
    print(f"Prompt: {prompt!r}, Generated text: {generated_text!r}")
```

To perform the same with an online mode launch the server:

```
python -m vllm.entrypoints.openai.api_server --host 0.0.0.0 --port 8000 --model_
↪ facebook/opt-6.7b \
  --seed 42 -tp 1 --speculative_model facebook/opt-125m --use-v2-block-manager \
  --num_speculative_tokens 5 --gpu_memory_utilization 0.8
```

Then use a client:

```
from openai import OpenAI

# Modify OpenAI's API key and API base to use vLLM's API server.
openai_api_key = "EMPTY"
openai_api_base = "http://localhost:8000/v1"

client = OpenAI(
    # defaults to os.environ.get("OPENAI_API_KEY")
    api_key=openai_api_key,
    base_url=openai_api_base,
)

models = client.models.list()
model = models.data[0].id

# Completion API
stream = False
completion = client.completions.create(
    model=model,
    prompt="The future of AI is",
    echo=False,
    n=1,
    stream=stream,
)

print("Completion results:")
if stream:
    for c in completion:
        print(c)
else:
    print(completion)
```

1.27.2 Speculating by matching n-grams in the prompt

The following code configures vLLM to use speculative decoding where proposals are generated by matching n-grams in the prompt. For more information read [this thread](#).

```
from vllm import LLM, SamplingParams

prompts = [
    "The future of AI is",
]
sampling_params = SamplingParams(temperature=0.8, top_p=0.95)
```

(continues on next page)

(continued from previous page)

```

llm = LLM(
    model="facebook/opt-6.7b",
    tensor_parallel_size=1,
    speculative_model="[ngram]",
    num_speculative_tokens=5,
    ngram_prompt_lookup_max=4,
    use_v2_block_manager=True,
)
outputs = llm.generate(prompts, sampling_params)

for output in outputs:
    prompt = output.prompt
    generated_text = output.outputs[0].text
    print(f"Prompt: {prompt!r}, Generated text: {generated_text!r}")

```

1.27.3 Speculating using MLP speculators

The following code configures vLLM to use speculative decoding where proposals are generated by draft models that conditioning draft predictions on both context vectors and sampled tokens. For more information see [this blog](#) or [this technical report](#).

```

from vllm import LLM, SamplingParams

prompts = [
    "The future of AI is",
]
sampling_params = SamplingParams(temperature=0.8, top_p=0.95)

llm = LLM(
    model="meta-llama/Meta-Llama-3.1-70B-Instruct",
    tensor_parallel_size=4,
    speculative_model="ibm-fms/llama3-70b-accelerator",
    speculative_draft_tensor_parallel_size=1,
    use_v2_block_manager=True,
)
outputs = llm.generate(prompts, sampling_params)

for output in outputs:
    prompt = output.prompt
    generated_text = output.outputs[0].text
    print(f"Prompt: {prompt!r}, Generated text: {generated_text!r}")

```

Note that these speculative models currently need to be run without tensor parallelism, although it is possible to run the main model using tensor parallelism (see example above). Since the speculative models are relatively small, we still see significant speedups. However, this limitation will be fixed in a future release.

A variety of speculative models of this type are available on HF hub:

- llama-13b-accelerator
- llama3-8b-accelerator
- codellama-34b-accelerator

- llama2-70b-accelerator
- llama3-70b-accelerator
- granite-3b-code-instruct-accelerator
- granite-8b-code-instruct-accelerator
- granite-7b-instruct-accelerator
- granite-20b-code-instruct-accelerator

1.27.4 Lossless guarantees of Speculative Decoding

In vLLM, speculative decoding aims to enhance inference efficiency while maintaining accuracy. This section addresses the lossless guarantees of speculative decoding, breaking down the guarantees into three key areas:

1. **Theoretical Losslessness** - Speculative decoding sampling is theoretically lossless up to the precision limits of hardware numerics. Floating-point errors might cause slight variations in output distributions, as discussed in [Accelerating Large Language Model Decoding with Speculative Sampling](#)
2. **Algorithmic Losslessness** - vLLM's implementation of speculative decoding is algorithmically validated to be lossless. Key validation tests include:
 - **Rejection Sampler Convergence**: Ensures that samples from vLLM's rejection sampler align with the target distribution. [View Test Code](#)
 - **Greedy Sampling Equality**: Confirms that greedy sampling with speculative decoding matches greedy sampling without it. This verifies that vLLM's speculative decoding framework, when integrated with the vLLM forward pass and the vLLM rejection sampler, provides a lossless guarantee. Almost all of the tests in [this directory](#) verify this property using [this assertion implementation](#)
3. **vLLM Logprob Stability** - vLLM does not currently guarantee stable token log probabilities (logprobs). This can result in different outputs for the same request across runs. For more details, see the FAQ section titled *Can the output of a prompt vary across runs in vLLM?* in the [FAQs](#).

Conclusion

While vLLM strives to ensure losslessness in speculative decoding, variations in generated outputs with and without speculative decoding can occur due to following factors:

- **Floating-Point Precision**: Differences in hardware numerical precision may lead to slight discrepancies in the output distribution.
- **Batch Size and Numerical Stability**: Changes in batch size may cause variations in logprobs and output probabilities, potentially due to non-deterministic behavior in batched operations or numerical instability.

Mitigation Strategies

For mitigation strategies, please refer to the FAQ entry *Can the output of a prompt vary across runs in vLLM?* in the [FAQs](#).

1.27.5 Resources for vLLM contributors

- [A Hacker’s Guide to Speculative Decoding in vLLM](#)
- [What is Lookahead Scheduling in vLLM?](#)
- [Information on batch expansion](#)
- [Dynamic speculative decoding](#)

1.28 Performance and Tuning

1.28.1 Preemption

Due to the auto-regressive nature of transformer architecture, there are times when KV cache space is insufficient to handle all batched requests. The vLLM can preempt requests to free up KV cache space for other requests. Preempted requests are recomputed when sufficient KV cache space becomes available again. When this occurs, the following warning is printed:

```
` WARNING 05-09 00:49:33 scheduler.py:1057] Sequence group 0 is preempted by
PreemptionMode.SWAP mode because there is not enough KV cache space. This can affect
the end-to-end performance. Increase gpu_memory_utilization or tensor_parallel_size to
provide more KV cache memory. total_cumulative_preemption_cnt=1 `
```

While this mechanism ensures system robustness, preemption and recomputation can adversely affect end-to-end latency. If you frequently encounter preemptions from the vLLM engine, consider the following actions:

- Increase *gpu_memory_utilization*. The vLLM pre-allocates GPU cache by using *gpu_memory_utilization%* of memory. By increasing this utilization, you can provide more KV cache space.
- Decrease *max_num_seqs* or *max_num_batched_tokens*. This can reduce the number of concurrent requests in a batch, thereby requiring less KV cache space.
- Increase *tensor_parallel_size*. This approach shards model weights, so each GPU has more memory available for KV cache.

You can also monitor the number of preemption requests through Prometheus metrics exposed by the vLLM. Additionally, you can log the cumulative number of preemption requests by setting `disable_log_stats=False`.

1.28.2 Chunked Prefill

vLLM supports an experimental feature chunked prefill. Chunked prefill allows to chunk large prefills into smaller chunks and batch them together with decode requests.

You can enable the feature by specifying `--enable-chunked-prefill` in the command line or setting `enable_chunked_prefill=True` in the LLM constructor.

```
llm = LLM(model="meta-llama/llama-2-7b-hf", enable_chunked_prefill=True)
# Set max_num_batched_tokens to tune performance.
# NOTE: 512 is the default max_num_batched_tokens for chunked prefill.
# llm = LLM(model="meta-llama/llama-2-7b-hf", enable_chunked_prefill=True, max_num_
↪ batched_tokens=512)
```

By default, vLLM scheduler prioritizes prefills and doesn’t batch prefill and decode to the same batch. This policy optimizes the TTFT (time to the first token), but incurs slower ITL (inter token latency) and inefficient GPU utilization.

Once chunked prefill is enabled, the policy is changed to prioritize decode requests. It batches all pending decode requests to the batch before scheduling any prefill. When there are available token_budget (`max_num_batched_tokens`), it schedules pending prefills. If a last pending prefill request cannot fit into `max_num_batched_tokens`, it chunks it.

This policy has two benefits:

- It improves ITL and generation decode because decode requests are prioritized.
- It helps achieve better GPU utilization by locating compute-bound (prefill) and memory-bound (decode) requests to the same batch.

You can tune the performance by changing `max_num_batched_tokens`. By default, it is set to 512, which has the best ITL on A100 in the initial benchmark (llama 70B and mixtral 8x22B). Smaller `max_num_batched_tokens` achieves better ITL because there are fewer prefills interrupting decodes. Higher `max_num_batched_tokens` achieves better TTFT as you can put more prefill to the batch.

- If `max_num_batched_tokens` is the same as `max_model_len`, that's almost the equivalent to the default scheduling policy (except that it still prioritizes decodes).
- Note that the default value (512) of `max_num_batched_tokens` is optimized for ITL, and it may have lower throughput than the default scheduler.

We recommend you set `max_num_batched_tokens > 2048` for throughput.

See related papers for more details (<https://arxiv.org/pdf/2401.08671> or <https://arxiv.org/pdf/2308.16369>).

Please try out this feature and let us know your feedback via GitHub issues!

1.29 Supported Hardware for Quantization Kernels

The table below shows the compatibility of various quantization implementations with different hardware platforms in vLLM:

Implementation	Volta	Turing	Ampere	Ada	Hopper	AMD GPU	Intel GPU	x86 CPU	AWS Inferentia	Google TPU
AWQ										
GPTQ										
Marlin (GPTQ/AWQ/FP8)										
INT8 (W8A8)										
FP8 (W8A8)										
AQLM										
bitsandbytes										
DeepSpeedFP										
GGUF										

1.29.1 Notes:

- Volta refers to SM 7.0, Turing to SM 7.5, Ampere to SM 8.0/8.6, Ada to SM 8.9, and Hopper to SM 9.0.
- “” indicates that the quantization method is supported on the specified hardware.
- “” indicates that the quantization method is not supported on the specified hardware.

Please note that this compatibility chart may be subject to change as vLLM continues to evolve and expand its support for different hardware platforms and quantization methods.

For the most up-to-date information on hardware support and quantization methods, please check the [quantization directory](#) or consult with the vLLM development team.

1.30 AutoAWQ

Warning: Please note that AWQ support in vLLM is under-optimized at the moment. We would recommend using the unquantized version of the model for better accuracy and higher throughput. Currently, you can use AWQ as a way to reduce memory footprint. As of now, it is more suitable for low latency inference with small number of concurrent requests. vLLM’s AWQ implementation have lower throughput than unquantized version.

To create a new 4-bit quantized model, you can leverage [AutoAWQ](#). Quantizing reduces the model’s precision from FP16 to INT4 which effectively reduces the file size by ~70%. The main benefits are lower latency and memory usage.

You can quantize your own models by installing AutoAWQ or picking one of the [400+ models on Huggingface](#).

```
$ pip install autoawq
```

After installing AutoAWQ, you are ready to quantize a model. Here is an example of how to quantize *mistralai/Mistral-7B-Instruct-v0.2*:

```
from awq import AutoAWQForCausalLM
from transformers import AutoTokenizer

model_path = 'mistralai/Mistral-7B-Instruct-v0.2'
quant_path = 'mistral-instruct-v0.2-awq'
quant_config = { "zero_point": True, "q_group_size": 128, "w_bit": 4, "version": "GEMM" }

# Load model
model = AutoAWQForCausalLM.from_pretrained(
    model_path, **{"low_cpu_mem_usage": True, "use_cache": False}
)
tokenizer = AutoTokenizer.from_pretrained(model_path, trust_remote_code=True)

# Quantize
model.quantize(tokenizer, quant_config=quant_config)

# Save quantized model
model.save_quantized(quant_path)
tokenizer.save_pretrained(quant_path)

print(f'Model is quantized and saved at "{quant_path}")
```

To run an AWQ model with vLLM, you can use `TheBloke/Llama-2-7b-Chat-AWQ` with the following command:

```
$ python examples/llm_engine_example.py --model TheBloke/Llama-2-7b-Chat-AWQ --
↳quantization awq
```

AWQ models are also supported directly through the LLM endpoint:

```
from vllm import LLM, SamplingParams

# Sample prompts.
prompts = [
    "Hello, my name is",
    "The president of the United States is",
    "The capital of France is",
    "The future of AI is",
]

# Create a sampling params object.
sampling_params = SamplingParams(temperature=0.8, top_p=0.95)

# Create an LLM.
llm = LLM(model="TheBloke/Llama-2-7b-Chat-AWQ", quantization="AWQ")
# Generate texts from the prompts. The output is a list of RequestOutput objects
# that contain the prompt, generated text, and other information.
outputs = llm.generate(prompts, sampling_params)
# Print the outputs.
for output in outputs:
    prompt = output.prompt
    generated_text = output.outputs[0].text
    print(f"Prompt: {prompt!r}, Generated text: {generated_text!r}")
```

1.31 BitsAndBytes

vLLM now supports `BitsAndBytes` for more efficient model inference. `BitsAndBytes` quantizes models to reduce memory usage and enhance performance without significantly sacrificing accuracy. Compared to other quantization methods, `BitsAndBytes` eliminates the need for calibrating the quantized model with input data.

Below are the steps to utilize `BitsAndBytes` with vLLM.

```
$ pip install bitsandbytes>=0.42.0
```

vLLM reads the model's config file and supports both in-flight quantization and pre-quantized checkpoint.

You can find `bitsandbytes` quantized models on <https://huggingface.co/models?other=bitsandbytes>. And usually, these repositories have a `config.json` file that includes a `quantization_config` section.

1.31.1 Read quantized checkpoint.

```
from vllm import LLM
import torch
# unsloth/tinyllama-bnb-4bit is a pre-quantized checkpoint.
model_id = "unsloth/tinyllama-bnb-4bit"
llm = LLM(model=model_id, dtype=torch.bfloat16, trust_remote_code=True, \
quantization="bitsandbytes", load_format="bitsandbytes")
```

1.31.2 Inflight quantization: load as 4bit quantization

```
from vllm import LLM
import torch
model_id = "huggyllama/llama-7b"
llm = LLM(model=model_id, dtype=torch.bfloat16, trust_remote_code=True, \
quantization="bitsandbytes", load_format="bitsandbytes")
```

1.32 INT8 W8A8

vLLM supports quantizing weights and activations to INT8 for memory savings and inference acceleration. This quantization method is particularly useful for reducing model size while maintaining good performance.

Please visit the HF collection of [quantized INT8 checkpoints of popular LLMs ready to use with vLLM](#).

Note: INT8 computation is supported on NVIDIA GPUs with compute capability > 7.5 (Turing, Ampere, Ada Lovelace, Hopper).

1.32.1 Prerequisites

To use INT8 quantization with vLLM, you'll need to install the `llm-compressor` library:

```
$ pip install llmcompressor==0.1.0
```

1.32.2 Quantization Process

The quantization process involves four main steps:

1. Loading the model
2. Preparing calibration data
3. Applying quantization
4. Evaluating accuracy in vLLM

1. Loading the Model

Use `SparseAutoModelForCausalLM`, which wraps `AutoModelForCausalLM`, for saving and loading quantized models:

```
from llmcompressor.transformers import SparseAutoModelForCausalLM
from transformers import AutoTokenizer

MODEL_ID = "meta-llama/Meta-Llama-3-8B-Instruct"
model = SparseAutoModelForCausalLM.from_pretrained(
    MODEL_ID, device_map="auto", torch_dtype="auto",
)
tokenizer = AutoTokenizer.from_pretrained(MODEL_ID)
```

2. Preparing Calibration Data

When quantizing activations to INT8, you need sample data to estimate the activation scales. It's best to use calibration data that closely matches your deployment data. For a general-purpose instruction-tuned model, you can use a dataset like `ultrachat`:

```
from datasets import load_dataset

NUM_CALIBRATION_SAMPLES = 512
MAX_SEQUENCE_LENGTH = 2048

# Load and preprocess the dataset
ds = load_dataset("HuggingFaceH4/ultrachat_200k", split="train_sft")
ds = ds.shuffle(seed=42).select(range(NUM_CALIBRATION_SAMPLES))

def preprocess(example):
    return {"text": tokenizer.apply_chat_template(example["messages"], tokenize=False)}
ds = ds.map(preprocess)

def tokenize(sample):
    return tokenizer(sample["text"], padding=False, max_length=MAX_SEQUENCE_LENGTH,
    ↪truncation=True, add_special_tokens=False)
ds = ds.map(tokenize, remove_columns=ds.column_names)
```

3. Applying Quantization

Now, apply the quantization algorithms:

```
from llmcompressor.transformers import oneshot
from llmcompressor.modifiers.quantization import GPTQModifier
from llmcompressor.modifiers.smoothquant import SmoothQuantModifier

# Configure the quantization algorithms
recipe = [
    SmoothQuantModifier(smoothing_strength=0.8),
    GPTQModifier(targets="Linear", scheme="W8A8", ignore=["lm_head"]),
]
```

(continues on next page)

(continued from previous page)

```

# Apply quantization
oneshot(
    model=model,
    dataset=ds,
    recipe=recipe,
    max_seq_length=MAX_SEQUENCE_LENGTH,
    num_calibration_samples=NUM_CALIBRATION_SAMPLES,
)

# Save the compressed model
SAVE_DIR = MODEL_ID.split("/") [1] + "-W8A8-Dynamic-Per-Token"
model.save_pretrained(SAVE_DIR, save_compressed=True)
tokenizer.save_pretrained(SAVE_DIR)

```

This process creates a W8A8 model with weights and activations quantized to 8-bit integers.

4. Evaluating Accuracy

After quantization, you can load and run the model in vLLM:

```

from vllm import LLM
model = LLM("./Meta-Llama-3-8B-Instruct-W8A8-Dynamic-Per-Token")

```

To evaluate accuracy, you can use `lm_eval`:

```

$ lm_eval --model vllm \
  --model_args pretrained="./Meta-Llama-3-8B-Instruct-W8A8-Dynamic-Per-Token",add_bos_
  token=true \
  --tasks gsm8k \
  --num_fewshot 5 \
  --limit 250 \
  --batch_size 'auto'

```

Note: Quantized models can be sensitive to the presence of the `bos` token. Make sure to include the `add_bos_token=True` argument when running evaluations.

1.32.3 Best Practices

- Start with 512 samples for calibration data (increase if accuracy drops)
- Use a sequence length of 2048 as a starting point
- Employ the chat template or instruction template that the model was trained with
- If you've fine-tuned a model, consider using a sample of your training data for calibration

1.32.4 Troubleshooting and Support

If you encounter any issues or have feature requests, please open an issue on the `vllm-project/llm-compressor` GitHub repository.

1.33 FP8 W8A8

vLLM supports FP8 (8-bit floating point) weight and activation quantization using hardware acceleration on GPUs such as Nvidia H100 and AMD MI300x. Currently, only Hopper and Ada Lovelace GPUs are officially supported for W8A8. Ampere GPUs are supported for W8A16 (weight-only FP8) utilizing Marlin kernels. Quantization of models with FP8 allows for a 2x reduction in model memory requirements and up to a 1.6x improvement in throughput with minimal impact on accuracy.

Please visit the HF collection of [quantized FP8 checkpoints of popular LLMs ready to use with vLLM](#).

The FP8 types typically supported in hardware have two distinct representations, each useful in different scenarios:

- **E4M3**: Consists of 1 sign bit, 4 exponent bits, and 3 bits of mantissa. It can store values up to +/-448 and nan.
- **E5M2**: Consists of 1 sign bit, 5 exponent bits, and 2 bits of mantissa. It can store values up to +/-57344, +/- inf, and nan. The tradeoff for the increased dynamic range is lower precision of the stored values.

Note: FP8 computation is supported on NVIDIA GPUs with compute capability > 8.9 (Ada Lovelace, Hopper). FP8 models will run on compute capability > 8.0 (Ampere) as weight-only W8A16, utilizing FP8 Marlin.

1.33.1 Quick Start with Online Dynamic Quantization

Dynamic quantization of an original precision BF16/FP16 model to FP8 can be achieved with vLLM without any calibration data required. You can enable the feature by specifying `--quantization="fp8"` in the command line or setting `quantization="fp8"` in the LLM constructor.

In this mode, all Linear modules (except for the final `lm_head`) have their weights quantized down to FP8_E4M3 precision with a per-tensor scale. Activations have their minimum and maximum values calculated during each forward pass to provide a dynamic per-tensor scale for high accuracy. As a result, latency improvements are limited in this mode.

```
from vllm import LLM
model = LLM("facebook/opt-125m", quantization="fp8")
# INFO 06-10 17:55:42 model_runner.py:157] Loading model weights took 0.1550 GB
result = model.generate("Hello, my name is")
```

Warning: Currently, we load the model at original precision before quantizing down to 8-bits, so you need enough memory to load the whole model.

1.33.2 Installation

To produce performant FP8 quantized models with vLLM, you'll need to install the `llm-compressor` library:

```
$ pip install llmcompressor==0.1.0
```

1.33.3 Quantization Process

The quantization process involves three main steps:

1. Loading the model
2. Applying quantization
3. Evaluating accuracy in vLLM

1. Loading the Model

Use `SparseAutoModelForCausalLM`, which wraps `AutoModelForCausalLM`, for saving and loading quantized models:

```
from llmcompressor.transformers import SparseAutoModelForCausalLM
from transformers import AutoTokenizer

MODEL_ID = "meta-llama/Meta-Llama-3-8B-Instruct"

model = SparseAutoModelForCausalLM.from_pretrained(
    MODEL_ID, device_map="auto", torch_dtype="auto")
tokenizer = AutoTokenizer.from_pretrained(MODEL_ID)
```

2. Applying Quantization

For FP8 quantization, we can recover accuracy with simple RTN quantization. We recommend targeting all `Linear` layers using the `FP8_DYNAMIC` scheme, which uses:

- Static, per-channel quantization on the weights
- Dynamic, per-token quantization on the activations

Since simple RTN does not require data for weight quantization and the activations are quantized dynamically, we do not need any calibration data for this quantization flow.

```
from llmcompressor.transformers import oneshot
from llmcompressor.modifiers.quantization import QuantizationModifier

# Configure the simple PTQ quantization
recipe = QuantizationModifier(
    targets="Linear", scheme="FP8_DYNAMIC", ignore=["lm_head"])

# Apply the quantization algorithm.
oneshot(model=model, recipe=recipe)

# Save the model.
```

(continues on next page)

(continued from previous page)

```
SAVE_DIR = MODEL_ID.split("/")[-1] + "-FP8-Dynamic"
model.save_pretrained(SAVE_DIR)
tokenizer.save_pretrained(SAVE_DIR)
```

3. Evaluating Accuracy

Install `vllm` and `lm-evaluation-harness`:

```
$ pip install vllm lm_eval==0.4.3
```

Load and run the model in `vllm`:

```
from vllm import LLM
model = LLM("./Meta-Llama-3-8B-Instruct-FP8-Dynamic")
model.generate("Hello my name is")
```

Evaluate accuracy with `lm_eval` (for example on 250 samples of `gsm8k`):

Note: Quantized models can be sensitive to the presence of the `bos` token. `lm_eval` does not add a `bos` token by default, so make sure to include the `add_bos_token=True` argument when running your evaluations.

```
$ MODEL=$PWD/Meta-Llama-3-8B-Instruct-FP8-Dynamic
$ lm_eval \
  --model vllm \
  --model_args pretrained=$MODEL,add_bos_token=True \
  --tasks gsm8k --num_fewshot 5 --batch_size auto --limit 250
```

Here's an example of the resulting scores:

Tasks	Version	Filter	n-shot	Metric	Value	Stderr
gsm8k	3	flexible-extract	5	exact_match ↑	0.768 ±	0.0268
		strict-match		5 exact_match ↑	0.768 ±	0.0268

1.33.4 Troubleshooting and Support

If you encounter any issues or have feature requests, please open an issue on the [vllm-project/llm-compressor](https://github.com/vllm-project/llm-compressor) GitHub repository.

1.33.5 Deprecated Flow

Note: The following information is preserved for reference and search purposes. The quantization method described below is deprecated in favor of the `llmcompressor` method described above.

For static per-tensor offline quantization to FP8, please install the [AutoFP8](#) library.

```
git clone https://github.com/neuralmagic/AutoFP8.git
pip install -e AutoFP8
```

This package introduces the `AutoFP8ForCausalLM` and `BaseQuantizeConfig` objects for managing how your model will be compressed.

1.33.6 Offline Quantization with Static Activation Scaling Factors

You can use `AutoFP8` with calibration data to produce per-tensor static scales for both the weights and activations by enabling the `activation_scheme="static"` argument.

```
from datasets import load_dataset
from transformers import AutoTokenizer
from auto_fp8 import AutoFP8ForCausalLM, BaseQuantizeConfig

pretrained_model_dir = "meta-llama/Meta-Llama-3-8B-Instruct"
quantized_model_dir = "Meta-Llama-3-8B-Instruct-FP8"

tokenizer = AutoTokenizer.from_pretrained(pretrained_model_dir, use_fast=True)
tokenizer.pad_token = tokenizer.eos_token

# Load and tokenize 512 dataset samples for calibration of activation scales
ds = load_dataset("mgoin/ultrachat_2k", split="train_sft").select(range(512))
examples = [tokenizer.apply_chat_template(batch["messages"], tokenize=False) for batch_
↳ in ds]
examples = tokenizer(examples, padding=True, truncation=True, return_tensors="pt").to(
↳ "cuda")

# Define quantization config with static activation scales
quantize_config = BaseQuantizeConfig(quant_method="fp8", activation_scheme="static")

# Load the model, quantize, and save checkpoint
model = AutoFP8ForCausalLM.from_pretrained(pretrained_model_dir, quantize_config)
model.quantize(examples)
model.save_quantized(quantized_model_dir)
```

Your model checkpoint with quantized weights and activations should be available at `Meta-Llama-3-8B-Instruct-FP8/`. Finally, you can load the quantized model checkpoint directly in `vLLM`.

```
from vllm import LLM
model = LLM(model="Meta-Llama-3-8B-Instruct-FP8/")
# INFO 06-10 21:15:41 model_runner.py:159] Loading model weights took 8.4596 GB
result = model.generate("Hello, my name is")
```

1.34 FP8 E5M2 KV Cache

The int8/int4 quantization scheme requires additional scale GPU memory storage, which reduces the expected GPU memory benefits. The FP8 data format retains 2~3 mantissa bits and can convert float/fp16/bfloat16 and fp8 to each other.

Here is an example of how to enable this feature:

```
from vllm import LLM, SamplingParams
# Sample prompts.
prompts = [
    "Hello, my name is",
    "The president of the United States is",
    "The capital of France is",
    "The future of AI is",
]
# Create a sampling params object.
sampling_params = SamplingParams(temperature=0.8, top_p=0.95)
# Create an LLM.
llm = LLM(model="facebook/opt-125m", kv_cache_dtype="fp8")
# Generate texts from the prompts. The output is a list of RequestOutput objects
# that contain the prompt, generated text, and other information.
outputs = llm.generate(prompts, sampling_params)
# Print the outputs.
for output in outputs:
    prompt = output.prompt
    generated_text = output.outputs[0].text
    print(f"Prompt: {prompt!r}, Generated text: {generated_text!r}")
```

1.35 FP8 E4M3 KV Cache

Quantizing the KV cache to FP8 reduces its memory footprint. This increases the number of tokens that can be stored in the cache, improving throughput. OCP (Open Compute Project www.opencompute.org) specifies two common 8-bit floating point data formats: E5M2 (5 exponent bits and 2 mantissa bits) and E4M3FN (4 exponent bits and 3 mantissa bits), often shortened as E4M3. One benefit of the E4M3 format over E5M2 is that floating point numbers are represented in higher precision. However, the small dynamic range of FP8 E4M3 (± 240.0 can be represented) typically necessitates the use of a higher-precision (typically FP32) scaling factor alongside each quantized tensor. For now, only per-tensor (scalar) scaling factors are supported. Development is ongoing to support scaling factors of a finer granularity (e.g. per-channel).

These scaling factors can be specified by passing an optional quantization param JSON to the LLM engine at load time. If this JSON is not specified, scaling factors default to 1.0. These scaling factors are typically obtained when running an unquantized model through a quantizer tool (e.g. AMD quantizer or NVIDIA AMMO).

To install AMMO (Algorithmic Model Optimization):

```
$ pip install --no-cache-dir --extra-index-url https://pypi.nvidia.com nvidia-ammo
```

Studies have shown that FP8 E4M3 quantization typically only minimally degrades inference accuracy. The most recent silicon offerings e.g. AMD MI300, NVIDIA Hopper or later support native hardware conversion to and from fp32, fp16, bf16, etc. Thus, LLM inference is greatly accelerated with minimal accuracy loss.

Here is an example of how to enable this feature:

```

# two float8_e4m3fn kv cache scaling factor files are provided under tests/fp8_kv,
↳ please refer to
# https://github.com/vllm-project/vllm/blob/main/examples/fp8/README.md to generate kv_
↳ cache_scales.json of your own.

from vllm import LLM, SamplingParams
sampling_params = SamplingParams(temperature=1.3, top_p=0.8)
llm = LLM(model="meta-llama/Llama-2-7b-chat-hf",
          kv_cache_dtype="fp8",
          quantization_param_path="./tests/fp8_kv/llama2-7b-fp8-kv/kv_cache_scales.json")
prompt = "London is the capital of"
out = llm.generate(prompt, sampling_params)[0].outputs[0].text
print(out)

# output w/ scaling factors: England, the United Kingdom, and one of the world's leading
↳ financial,
# output w/o scaling factors: England, located in the southeastern part of the country.
↳ It is known

```

1.36 Introduction

1.36.1 What is Automatic Prefix Caching

Automatic Prefix Caching (APC in short) caches the KV cache of existing queries, so that a new query can directly reuse the KV cache if it shares the same prefix with one of the existing queries, allowing the new query to skip the computation of the shared part.

Note: Technical details on how vLLM implements APC are in the next page.

1.36.2 Enabling APC in vLLM

Set `enable_prefix_caching=True` in vLLM engine to enable APC. Here is an example:

```

import time
from vllm import LLM, SamplingParams

# A prompt containing a large markdown table. The table is randomly generated by GPT-4.
LONG_PROMPT = "You are a helpful assistant in recognizes the content of tables in
↳ markdown format. Here is a table as follows.\n# Table\n" + ""
| ID | Name | Age | Occupation | Country | Email |
↳ Phone Number | Address |
|----|-----|----|-----|-----|-----|
↳ -----|-----|
| 1 | John Doe | 29 | Engineer | USA | john.doe@example.com |
↳ 555-1234 | 123 Elm St, Springfield, IL |
| 2 | Jane Smith | 34 | Doctor | Canada | jane.smith@example.com |
↳ 555-5678 | 456 Oak St, Toronto, ON |

```

1.36.3 Example workloads

We describe two example workloads, where APC can provide huge performance benefit:

- Long document query, where the user repeatedly queries the same long document (e.g. software manual or annual report) with different queries. In this case, instead of processing the long document again and again, APC allows vLLM to process this long document *only once*, and all future requests can avoid recomputing this long document by reusing its KV cache. This allows vLLM to serve future requests with much higher throughput and much lower latency.
- Multi-round conversation, where the user may chat with the application multiple times in the same chatting session. In this case, instead of processing the whole chatting history again and again, APC allows vLLM to reuse the processing results of the chat history across all future rounds of conversation, allowing vLLM to serve future requests with much higher throughput and much lower latency.

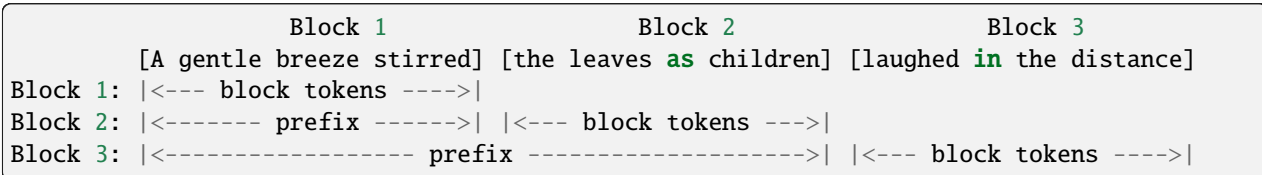

1.36.4 Limits

APC in general does not reduce the performance of vLLM. With that being said, APC only reduces the time of processing the queries (the prefilling phase) and does not reduce the time of generating new tokens (the decoding phase). So APC does not bring performance gain when vLLM spends most of the time generating answers to the queries (e.g. when the length of the answer is long), or new queries do not share the same prefix with any of existing queries (so that the computation cannot be reused).

1.37 Implementation

The core idea of PagedAttention is to partition the KV cache of each request into KV Blocks. Each block contains the attention keys and values for a fixed number of tokens. The PagedAttention algorithm allows these blocks to be stored in non-contiguous physical memory so that we can eliminate memory fragmentation by allocating the memory on demand.

To automatically cache the KV cache, we utilize the following key observation: Each KV block can be uniquely identified by the tokens within the block and the tokens in the prefix before the block.

In the example above, the KV cache in the first block can be uniquely identified with the tokens “A gentle breeze stirred”. The third block can be uniquely identified with the tokens in the block “laughed in the distance”, along with the prefix tokens “A gentle breeze stirred the leaves as children”. Therefore, we can build the following one-to-one mapping:

```
hash(prefix tokens + block tokens) <--> KV Block
```

With this mapping, we can add another indirection in vLLM’s KV cache management. Previously, each sequence in vLLM maintained a mapping from their logical KV blocks to physical blocks. To achieve automatic caching of KV blocks, we map the logical KV blocks to their hash value and maintain a global hash table of all the physical blocks. In this way, all the KV blocks sharing the same hash value (e.g., shared prefix blocks across two requests) can be mapped to the same physical block and share the memory space.

This design achieves automatic prefix caching without the need of maintaining a tree structure among the KV blocks. More specifically, all of the blocks are independent of each other and can be allocated and freed by itself, which enables us to manage the KV cache as ordinary caches in operating system.

1.38 Generalized Caching Policy

Keeping all the KV blocks in a hash table enables vLLM to cache KV blocks from earlier requests to save memory and accelerate the computation of future requests. For example, if a new request shares the system prompt with the previous request, the KV cache of the shared prompt can directly be used for the new request without recomputation. However, the total KV cache space is limited and we have to decide which KV blocks to keep or evict when the cache is full.

Managing KV cache with a hash table allows us to implement flexible caching policies. As an example, in current vLLM, we implement the following eviction policy:

- When there are no free blocks left, we will evict a KV block with reference count (i.e., number of current requests using the block) equals 0.
- If there are multiple blocks with reference count equals to 0, we prioritize to evict the least recently used block (LRU).
- If there are multiple blocks whose last access time are the same, we prioritize the eviction of the block that is at the end of the longest prefix (i.e., has the maximum number of blocks before it).

Note that this eviction policy effectively implements the exact policy as in [RadixAttention](#) when applied to models with full attention, which prioritizes to evict reference count zero and least recent used leaf nodes in the prefix tree.

However, the hash-based KV cache management gives us the flexibility to handle more complicated serving scenarios and implement more complicated eviction policies beyond the policy above:

- **Multi-LoRA serving.** When serving requests for multiple LoRA adapters, we can simply let the hash of each KV block to also include the LoRA ID the request is querying for to enable caching for all adapters. In this way, we can jointly manage the KV blocks for different adapters, which simplifies the system implementation and improves the global cache hit rate and efficiency.
- **Multi-modal models.** When the user input includes more than just discrete tokens, we can use different hashing methods to handle the caching of inputs of different modalities. For example, perceptual hashing for images to cache similar input images.

1.39 Benchmark suites of vLLM

vLLM contains two sets of benchmarks:

- **Performance benchmarks:** benchmark vLLM's performance under various workloads at a high frequency (when a pull request (PR for short) of vLLM is being merged). See [vLLM performance dashboard](#) for the latest performance results.
- **Nightly benchmarks:** compare vLLM's performance against alternatives (tgi, trt-llm, and lmdeploy) when there are major updates of vLLM (e.g., bumping up to a new version). The latest results are available in the [vLLM GitHub README](#).

1.39.1 Trigger a benchmark

The performance benchmarks and nightly benchmarks can be triggered by submitting a PR to vLLM, and label the PR with *perf-benchmarks* and *nightly-benchmarks*.

Note: Please refer to [vLLM performance benchmark descriptions](#) and [vLLM nightly benchmark descriptions](#) for detailed descriptions on benchmark environment, workload and metrics.

1.40 Sampling Parameters

```
class vllm.SamplingParams(n: int = 1, best_of: int | None = None, presence_penalty: float = 0.0,
                        frequency_penalty: float = 0.0, repetition_penalty: float = 1.0, temperature: float =
                        1.0, top_p: float = 1.0, top_k: int = -1, min_p: float = 0.0, seed: int | None = None,
                        use_beam_search: bool = False, length_penalty: float = 1.0, early_stopping: bool
                        | str = False, stop: str | ~typing.List[str] | None = None, stop_token_ids:
                        ~typing.List[int] | None = None, ignore_eos: bool = False, max_tokens: int | None
                        = 16, min_tokens: int = 0, logprobs: int | None = None, prompt_logprobs: int |
                        None = None, detokenize: bool = True, skip_special_tokens: bool = True,
                        spaces_between_special_tokens: bool = True, logits_processors: ~typing.Any |
                        None = None, include_stop_str_in_output: bool = False, truncate_prompt_tokens:
                        int[int] | None = None, output_kind: ~vllm.sampling_params.RequestOutputKind
                        = RequestOutputKind.CUMULATIVE, output_text_buffer_length: int = 0,
                        _all_stop_token_ids: ~typing.Set[int] = <factory>)
```

Sampling parameters for text generation.

Overall, we follow the sampling parameters from the OpenAI text completion API (<https://platform.openai.com/docs/api-reference/completions/create>). In addition, we support beam search, which is not supported by OpenAI.

Parameters

- **n** – Number of output sequences to return for the given prompt.
- **best_of** – Number of output sequences that are generated from the prompt. From these *best_of* sequences, the top *n* sequences are returned. *best_of* must be greater than or equal to *n*. This is treated as the beam width when *use_beam_search* is True. By default, *best_of* is set to *n*.
- **presence_penalty** – Float that penalizes new tokens based on whether they appear in the generated text so far. Values > 0 encourage the model to use new tokens, while values < 0 encourage the model to repeat tokens.
- **frequency_penalty** – Float that penalizes new tokens based on their frequency in the generated text so far. Values > 0 encourage the model to use new tokens, while values < 0 encourage the model to repeat tokens.
- **repetition_penalty** – Float that penalizes new tokens based on whether they appear in the prompt and the generated text so far. Values > 1 encourage the model to use new tokens, while values < 1 encourage the model to repeat tokens.
- **temperature** – Float that controls the randomness of the sampling. Lower values make the model more deterministic, while higher values make the model more random. Zero means greedy sampling.
- **top_p** – Float that controls the cumulative probability of the top tokens to consider. Must be in (0, 1]. Set to 1 to consider all tokens.

- **top_k** – Integer that controls the number of top tokens to consider. Set to -1 to consider all tokens.
- **min_p** – Float that represents the minimum probability for a token to be considered, relative to the probability of the most likely token. Must be in [0, 1]. Set to 0 to disable this.
- **seed** – Random seed to use for the generation.
- **use_beam_search** – Whether to use beam search instead of sampling.
- **length_penalty** – Float that penalizes sequences based on their length. Used in beam search.
- **early_stopping** – Controls the stopping condition for beam search. It accepts the following values: *True*, where the generation stops as soon as there are *best_of* complete candidates; *False*, where an heuristic is applied and the generation stops when is it very unlikely to find better candidates; *“never”*, where the beam search procedure only stops when there cannot be better candidates (canonical beam search algorithm).
- **stop** – List of strings that stop the generation when they are generated. The returned output will not contain the stop strings.
- **stop_token_ids** – List of tokens that stop the generation when they are generated. The returned output will contain the stop tokens unless the stop tokens are special tokens.
- **include_stop_str_in_output** – Whether to include the stop strings in output text. Defaults to False.
- **ignore_eos** – Whether to ignore the EOS token and continue generating tokens after the EOS token is generated.
- **max_tokens** – Maximum number of tokens to generate per output sequence.
- **min_tokens** – Minimum number of tokens to generate per output sequence before EOS or stop_token_ids can be generated
- **logprobs** – Number of log probabilities to return per output token. When set to None, no probability is returned. If set to a non-None value, the result includes the log probabilities of the specified number of most likely tokens, as well as the chosen tokens. Note that the implementation follows the OpenAI API: The API will always return the log probability of the sampled token, so there may be up to *logprobs+1* elements in the response.
- **prompt_logprobs** – Number of log probabilities to return per prompt token.
- **detokenize** – Whether to detokenize the output. Defaults to True.
- **skip_special_tokens** – Whether to skip special tokens in the output.
- **spaces_between_special_tokens** – Whether to add spaces between special tokens in the output. Defaults to True.
- **logits_processors** – List of functions that modify logits based on previously generated tokens, and optionally prompt tokens as a first argument.
- **truncate_prompt_tokens** – If set to an integer k, will use only the last k tokens from the prompt (i.e., left truncation). Defaults to None (i.e., no truncation).

`clone()` → *SamplingParams*

Deep copy excluding LogitsProcessor objects.

LogitsProcessor objects are excluded because they may contain an arbitrary, nontrivial amount of data. See <https://github.com/vllm-project/vllm/issues/3087>

```
update_from_generation_config(generation_config: Dict[str, Any], model_eos_token_id: int | None = None) → None
```

Update if there are non-default values from generation_config

1.41 Offline Inference

1.41.1 LLM Class

```
class vllm.LLM(model: str, tokenizer: str | None = None, tokenizer_mode: str = 'auto', skip_tokenizer_init: bool = False, trust_remote_code: bool = False, tensor_parallel_size: int = 1, dtype: str = 'auto', quantization: str | None = None, revision: str | None = None, tokenizer_revision: str | None = None, seed: int = 0, gpu_memory_utilization: float = 0.9, swap_space: float = 4, cpu_offload_gb: float = 0, enforce_eager: bool | None = None, max_context_len_to_capture: int | None = None, max_seq_len_to_capture: int = 8192, disable_custom_all_reduce: bool = False, disable_async_output_proc: bool = False, **kwargs)
```

An LLM for generating texts from given prompts and sampling parameters.

This class includes a tokenizer, a language model (possibly distributed across multiple GPUs), and GPU memory space allocated for intermediate states (aka KV cache). Given a batch of prompts and sampling parameters, this class generates texts from the model, using an intelligent batching mechanism and efficient memory management.

Parameters

- **model** – The name or path of a HuggingFace Transformers model.
- **tokenizer** – The name or path of a HuggingFace Transformers tokenizer.
- **tokenizer_mode** – The tokenizer mode. “auto” will use the fast tokenizer if available, and “slow” will always use the slow tokenizer.
- **skip_tokenizer_init** – If true, skip initialization of tokenizer and detokenizer. Expect valid prompt_token_ids and None for prompt from the input.
- **trust_remote_code** – Trust remote code (e.g., from HuggingFace) when downloading the model and tokenizer.
- **tensor_parallel_size** – The number of GPUs to use for distributed execution with tensor parallelism.
- **dtype** – The data type for the model weights and activations. Currently, we support *float32*, *float16*, and *bfloat16*. If *auto*, we use the *torch_dtype* attribute specified in the model config file. However, if the *torch_dtype* in the config is *float32*, we will use *float16* instead.
- **quantization** – The method used to quantize the model weights. Currently, we support “awq”, “gptq”, and “fp8” (experimental). If None, we first check the *quantization_config* attribute in the model config file. If that is None, we assume the model weights are not quantized and use *dtype* to determine the data type of the weights.
- **revision** – The specific model version to use. It can be a branch name, a tag name, or a commit id.
- **tokenizer_revision** – The specific tokenizer version to use. It can be a branch name, a tag name, or a commit id.
- **seed** – The seed to initialize the random number generator for sampling.
- **gpu_memory_utilization** – The ratio (between 0 and 1) of GPU memory to reserve for the model weights, activations, and KV cache. Higher values will increase the KV cache size

and thus improve the model's throughput. However, if the value is too high, it may cause out-of-memory (OOM) errors.

- **swap_space** – The size (GiB) of CPU memory per GPU to use as swap space. This can be used for temporarily storing the states of the requests when their *best_of* sampling parameters are larger than 1. If all requests will have *best_of=1*, you can safely set this to 0. Otherwise, too small values may cause out-of-memory (OOM) errors.
- **cpu_offload_gb** – The size (GiB) of CPU memory to use for offloading the model weights. This virtually increases the GPU memory space you can use to hold the model weights, at the cost of CPU-GPU data transfer for every forward pass.
- **enforce_eager** – Whether to enforce eager execution. If True, we will disable CUDA graph and always execute the model in eager mode. If False, we will use CUDA graph and eager execution in hybrid.
- **max_context_len_to_capture** – Maximum context len covered by CUDA graphs. When a sequence has context length larger than this, we fall back to eager mode (DEPRECATED. Use *max_seq_len_to_capture* instead).
- **max_seq_len_to_capture** – Maximum sequence len covered by CUDA graphs. When a sequence has context length larger than this, we fall back to eager mode.
- **disable_custom_all_reduce** – See `ParallelConfig`
- ****kwargs** – Arguments for `EngineArgs`. (See [Engine Arguments](#))

Note: This class is intended to be used for offline inference. For online serving, use the `AsyncLLMEngine` class instead.

DEPRECATE_LEGACY: ClassVar[bool] = False

A flag to toggle whether to deprecate the legacy generate/encode API.

chat(*messages: List[ChatCompletionSystemMessageParam | ChatCompletionUserMessageParam | ChatCompletionAssistantMessageParam | ChatCompletionToolMessageParam | ChatCompletionFunctionMessageParam | CustomChatCompletionMessageParam]*, *sampling_params: SamplingParams | List[SamplingParams] | None = None*, *use_tqdm: bool = True*, *lora_request: LoRARequest | None = None*, *chat_template: str | None = None*, *add_generation_prompt: bool = True*) → `List[RequestOutput]`

Generate responses for a chat conversation.

The chat conversation is converted into a text prompt using the tokenizer and calls the `generate()` method to generate the responses.

Multi-modal inputs can be passed in the same way you would pass them to the OpenAI API.

Parameters

- **messages** – A single conversation represented as a list of messages. Each message is a dictionary with 'role' and 'content' keys.
- **sampling_params** – The sampling parameters for text generation. If None, we use the default sampling parameters. When it is a single value, it is applied to every prompt. When it is a list, the list must have the same length as the prompts and it is paired one by one with the prompt.
- **use_tqdm** – Whether to use tqdm to display the progress bar.
- **lora_request** – LoRA request to use for generation, if any.

- **chat_template** – The template to use for structuring the chat. If not provided, the model’s default chat template will be used.
- **add_generation_prompt** – If True, adds a generation template to each message.

Returns

A list of `RequestOutput` objects containing the generated responses in the same order as the input messages.

```
encode(prompts: str, pooling_params: PoolingParams | Sequence[PoolingParams] | None = None,
        prompt_token_ids: List[int] | None = None, use_tqdm: bool = True, lora_request: List[LoRARequest]
        | LoRARequest | None = None) → List[EmbeddingRequestOutput]
```

```
encode(prompts: List[str], pooling_params: PoolingParams | Sequence[PoolingParams] | None = None,
        prompt_token_ids: List[List[int]] | None = None, use_tqdm: bool = True, lora_request:
        List[LoRARequest] | LoRARequest | None = None) → List[EmbeddingRequestOutput]
```

```
encode(prompts: str | None = None, pooling_params: PoolingParams | Sequence[PoolingParams] | None =
        None, *, prompt_token_ids: List[int], use_tqdm: bool = True, lora_request: List[LoRARequest] |
        LoRARequest | None = None) → List[EmbeddingRequestOutput]
```

```
encode(prompts: List[str] | None = None, pooling_params: PoolingParams | Sequence[PoolingParams] |
        None = None, *, prompt_token_ids: List[List[int]], use_tqdm: bool = True, lora_request:
        List[LoRARequest] | LoRARequest | None = None) → List[EmbeddingRequestOutput]
```

```
encode(prompts: None, pooling_params: None, prompt_token_ids: List[int] | List[List[int]], use_tqdm: bool
        = True, lora_request: List[LoRARequest] | LoRARequest | None = None) →
        List[EmbeddingRequestOutput]
```

```
encode(inputs: PromptInputs | Sequence[PromptInputs], /, *, pooling_params: PoolingParams |
        Sequence[PoolingParams] | None = None, use_tqdm: bool = True, lora_request: List[LoRARequest] |
        LoRARequest | None = None) → List[EmbeddingRequestOutput]
```

Generates the completions for the input prompts.

This class automatically batches the given prompts, considering the memory constraint. For the best performance, put all of your prompts into a single list and pass it to this method.

Parameters

- **inputs** – The inputs to the LLM. You may pass a sequence of inputs for batch inference. See [PromptInputs](#) for more details about the format of each input.
- **pooling_params** – The pooling parameters for pooling. If None, we use the default pooling parameters.
- **use_tqdm** – Whether to use tqdm to display the progress bar.
- **lora_request** – LoRA request to use for generation, if any.
- **prompt_adapter_request** – Prompt Adapter request to use for generation, if any.

Returns

A list of `EmbeddingRequestOutput` objects containing the generated embeddings in the same order as the input prompts.

Note: Using `prompts` and `prompt_token_ids` as keyword parameters is considered legacy and may be deprecated in the future. You should instead pass them via the `inputs` parameter.

```
generate(prompts: str, sampling_params: SamplingParams | List[SamplingParams] | None = None,
        prompt_token_ids: List[int] | None = None, use_tqdm: bool = True, lora_request:
        List[LoRARequest] | LoRARequest | None = None) → List[RequestOutput]
```

```

generate(prompts: List[str], sampling_params: SamplingParams | List[SamplingParams] | None = None,
           prompt_token_ids: List[List[int]] | None = None, use_tqdm: bool = True, lora_request:
           List[LoRARequest] | LoRARequest | None = None) → List[RequestOutput]

generate(prompts: str | None = None, sampling_params: SamplingParams | List[SamplingParams] | None =
           None, *, prompt_token_ids: List[int], use_tqdm: bool = True, lora_request: List[LoRARequest] |
           LoRARequest | None = None) → List[RequestOutput]

generate(prompts: List[str] | None = None, sampling_params: SamplingParams | List[SamplingParams] |
           None = None, *, prompt_token_ids: List[List[int]], use_tqdm: bool = True, lora_request:
           List[LoRARequest] | LoRARequest | None = None) → List[RequestOutput]

generate(prompts: None, sampling_params: None, prompt_token_ids: List[int] | List[List[int]], use_tqdm:
           bool = True, lora_request: List[LoRARequest] | LoRARequest | None = None) →
           List[RequestOutput]

generate(inputs: PromptInputs | Sequence[PromptInputs], /, *, sampling_params: SamplingParams |
           Sequence[SamplingParams] | None = None, use_tqdm: bool = True, lora_request:
           List[LoRARequest] | LoRARequest | None = None) → List[RequestOutput]

```

Generates the completions for the input prompts.

This class automatically batches the given prompts, considering the memory constraint. For the best performance, put all of your prompts into a single list and pass it to this method.

Parameters

- **inputs** – A list of inputs to generate completions for.
- **sampling_params** – The sampling parameters for text generation. If None, we use the default sampling parameters. When it is a single value, it is applied to every prompt. When it is a list, the list must have the same length as the prompts and it is paired one by one with the prompt.
- **use_tqdm** – Whether to use tqdm to display the progress bar.
- **lora_request** – LoRA request to use for generation, if any.
- **prompt_adapter_request** – Prompt Adapter request to use for generation, if any.

Returns

A list of RequestOutput objects containing the generated completions in the same order as the input prompts.

Note: Using `prompts` and `prompt_token_ids` as keyword parameters is considered legacy and may be deprecated in the future. You should instead pass them via the `inputs` parameter.

1.41.2 LLM Inputs

vllm.inputs.PromptInputs

The central part of internal API.

This represents a generic version of type ‘origin’ with type arguments ‘params’. There are two kind of these aliases: user defined and special. The special ones are wrappers around builtin collections and ABCs in `collections.abc`. These must have ‘name’ always set. If ‘inst’ is False, then the alias can’t be instantiated, this is used by e.g. `typing.List` and `typing.Dict`.

alias of `Union[str, TextPrompt, TokensPrompt, ExplicitEncoderDecoderPrompt]`

```
class vllm.inputs.TextPrompt
```

Bases: `TypedDict`

Schema for a text prompt.

prompt: `str`

The input text to be tokenized before passing to the model.

multi_modal_data: `typing_extensions.NotRequired[MultiModalDataDict]`

Optional multi-modal data to pass to the model, if the model supports it.

```
class vllm.inputs.TokensPrompt
```

Bases: `TypedDict`

Schema for a tokenized prompt.

prompt_token_ids: `List[int]`

A list of token IDs to pass to the model.

multi_modal_data: `typing_extensions.NotRequired[MultiModalDataDict]`

Optional multi-modal data to pass to the model, if the model supports it.

1.42 vLLM Engine

1.42.1 LLMEngine

```
class vllm.LLMEngine(model_config: ModelConfig, cache_config: CacheConfig, parallel_config:
    ParallelConfig, scheduler_config: SchedulerConfig, device_config: DeviceConfig,
    load_config: LoadConfig, lora_config: LoRAConfig | None, speculative_config:
    SpeculativeConfig | None, decoding_config: DecodingConfig | None,
    observability_config: ObservabilityConfig | None, prompt_adapter_config:
    PromptAdapterConfig | None, executor_class: Type[ExecutorBase], log_stats: bool,
    usage_context: UsageContext = UsageContext.ENGINE_CONTEXT, stat_loggers:
    Dict[str, StatLoggerBase] | None = None, input_registry: InputRegistry =
    INPUT_REGISTRY)
```

An LLM engine that receives requests and generates texts.

This is the main class for the vLLM engine. It receives requests from clients and generates texts from the LLM. It includes a tokenizer, a language model (possibly distributed across multiple GPUs), and GPU memory space allocated for intermediate states (aka KV cache). This class utilizes iteration-level scheduling and efficient memory management to maximize the serving throughput.

The `LLM` class wraps this class for offline batched inference and the `AsyncLLMEngine` class wraps this class for online serving.

The config arguments are derived from `EngineArgs`. (See [Engine Arguments](#))

Parameters

- **model_config** – The configuration related to the LLM model.
- **cache_config** – The configuration related to the KV cache memory management.
- **parallel_config** – The configuration related to distributed execution.
- **scheduler_config** – The configuration related to the request scheduler.
- **device_config** – The configuration related to the device.

- **lora_config** (*Optional*) – The configuration related to serving multi-LoRA.
- **speculative_config** (*Optional*) – The configuration related to speculative decoding.
- **executor_class** – The model executor class for managing distributed execution.
- **prompt_adapter_config** (*Optional*) – The configuration related to serving prompt adapters.
- **log_stats** – Whether to log statistics.
- **usage_context** – Specified entry point, used for usage info collection.

DO_VALIDATE_OUTPUT: `ClassVar[bool] = False`

A flag to toggle whether to validate the type of request output.

abort_request(*request_id: str | Iterable[str]*) → *None*

Aborts a request(s) with the given ID.

Parameters

request_id – The ID(s) of the request to abort.

Details:

- Refer to the `abort_seq_group()` from class `Scheduler`.

Example

```
>>> # initialize engine and add a request with request_id
>>> request_id = str(0)
>>> # abort the request
>>> engine.abort_request(request_id)
```

add_request(*request_id: str, inputs: str | TextPrompt | TokensPrompt | ExplicitEncoderDecoderPrompt, params: SamplingParams | PoolingParams, arrival_time: float | None = None, lora_request: LoRARequest | None = None, trace_headers: Mapping[str, str] | None = None, prompt_adapter_request: PromptAdapterRequest | None = None*) → *None*

Add a request to the engine's request pool.

The request is added to the request pool and will be processed by the scheduler as `engine.step()` is called. The exact scheduling policy is determined by the scheduler.

Parameters

- **request_id** – The unique ID of the request.
- **inputs** – The inputs to the LLM. See `PromptInputs` for more details about the format of each input.
- **params** – Parameters for sampling or pooling. `SamplingParams` for text generation. `PoolingParams` for pooling.
- **arrival_time** – The arrival time of the request. If `None`, we use the current monotonic time.
- **trace_headers** – OpenTelemetry trace headers.

Details:

- Set `arrival_time` to the current time if it is `None`.

- Set `prompt_token_ids` to the encoded prompt if it is `None`.
- Create `best_of` number of `Sequence` objects.
- Create a `SequenceGroup` object from the list of `Sequence`.
- Add the `SequenceGroup` object to the scheduler.

Example

```

>>> # initialize engine
>>> engine = LLMEngine.from_engine_args(engine_args)
>>> # set request arguments
>>> example_prompt = "Who is the president of the United States?"
>>> sampling_params = SamplingParams(temperature=0.0)
>>> request_id = 0
>>>
>>> # add the request to the engine
>>> engine.add_request(
>>>     str(request_id),
>>>     example_prompt,
>>>     SamplingParams(temperature=0.0))
>>> # continue the request processing
>>> ...

```

`do_log_stats(scheduler_outputs: SchedulerOutputs | None = None, model_output: List[SamplerOutput] | None = None, finished_before: List[int] | None = None, skip: List[int] | None = None) → None`

Forced log when no requests active.

`classmethod from_engine_args(engine_args: EngineArgs, usage_context: UsageContext = UsageContext.ENGINE_CONTEXT, stat_loggers: Dict[str, StatLoggerBase] | None = None) → LLMEngine`

Creates an LLM engine from the engine arguments.

`get_decoding_config()` → `DecodingConfig`

Gets the decoding configuration.

`get_lora_config()` → `LoRAConfig`

Gets the LoRA configuration.

`get_model_config()` → `ModelConfig`

Gets the model configuration.

`get_num_unfinished_requests()` → `int`

Gets the number of unfinished requests.

`get_parallel_config()` → `ParallelConfig`

Gets the parallel configuration.

`get_scheduler_config()` → `SchedulerConfig`

Gets the scheduler configuration.

`has_unfinished_requests()` → `bool`

Returns True if there are unfinished requests.

has_unfinished_requests_for_virtual_engine(*virtual_engine: int*) → bool

Returns True if there are unfinished requests for the virtual engine.

step() → List[RequestOutput | EmbeddingRequestOutput]

Performs one decoding iteration and returns newly generated results.

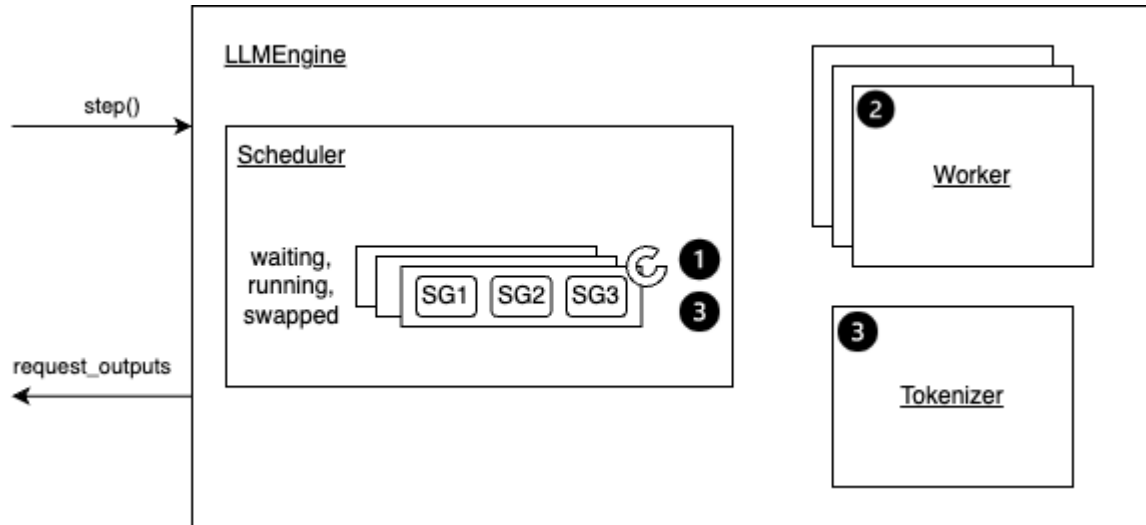

Fig. 1: Overview of the step function.

Details:

- Step 1: Schedules the sequences to be executed in the next iteration and the token blocks to be swapped in/out/copy.
 - Depending on the scheduling policy, sequences may be *preempted/reordered*.
 - A Sequence Group (SG) refer to a group of sequences that are generated from the same prompt.
- Step 2: Calls the distributed executor to execute the model.
- Step 3: Processes the model output. This mainly includes:
 - Decodes the relevant outputs.
 - Updates the scheduled sequence groups with model outputs based on its *sampling parameters* (*use_beam_search* or not).
 - Frees the finished sequence groups.
- Finally, it creates and returns the newly generated results.

Example

```
>>> # Please see the example/ folder for more detailed examples.
>>>
>>> # initialize engine and request arguments
>>> engine = LLMEngine.from_engine_args(engine_args)
>>> example_inputs = [(0, "What is LLM?",
>>>     SamplingParams(temperature=0.0))]
>>>
```

(continues on next page)

(continued from previous page)

```

>>> # Start the engine with an event loop
>>> while True:
>>>     if example_inputs:
>>>         req_id, prompt, sampling_params = example_inputs.pop(0)
>>>         engine.add_request(str(req_id), prompt, sampling_params)
>>>
>>>     # continue the request processing
>>>     request_outputs = engine.step()
>>>     for request_output in request_outputs:
>>>         if request_output.finished:
>>>             # return or show the request output
>>>
>>>     if not (engine.has_unfinished_requests() or example_inputs):
>>>         break

```

1.42.2 AsyncLLMEngine

```
class vllm.AsyncLLMEngine(worker_use_ray: bool, *args, log_requests: bool = True, start_engine_loop: bool = True, **kwargs)
```

An asynchronous wrapper for *LLMEngine*.

This class is used to wrap the *LLMEngine* class to make it asynchronous. It uses *asyncio* to create a background loop that keeps processing incoming requests. The *LLMEngine* is kicked by the *generate* method when there are requests in the waiting queue. The *generate* method yields the outputs from the *LLMEngine* to the caller.

Parameters

- **worker_use_ray** – Whether to use Ray for model workers. Required for distributed execution. Should be the same as *parallel_config.worker_use_ray*.
- **log_requests** – Whether to log the requests.
- **start_engine_loop** – If True, the background task to run the engine will be automatically started in the *generate* call.
- ***args** – Arguments for *LLMEngine*.
- ****kwargs** – Arguments for *LLMEngine*.

async abort(*request_id: str*) → None

Abort a request.

Abort a submitted request. If the request is finished or not found, this method will be a no-op.

Parameters

request_id – The unique id of the request.

async check_health() → None

Raises an error if engine is unhealthy.

async encode(*inputs: str | TextPrompt | TokensPrompt | ExplicitEncoderDecoderPrompt, pooling_params: PoolingParams, request_id: str, lora_request: LoRARequest | None = None, trace_headers: Mapping[str, str] | None = None*) → AsyncGenerator[EmbeddingRequestOutput, None]

Generate outputs for a request from an embedding model.

Generate outputs for a request. This method is a coroutine. It adds the request into the waiting queue of the *LLMEngine* and streams the outputs from the *LLMEngine* to the caller.

Parameters

- **inputs** – The inputs to the LLM. See *PromptInputs* for more details about the format of each input.
- **pooling_params** – The pooling parameters of the request.
- **request_id** – The unique id of the request.
- **lora_request** – LoRA request to use for generation, if any.
- **trace_headers** – OpenTelemetry trace headers.

Yields

The output *EmbeddingRequestOutput* objects from the LLMEngine for the request.

Details:

- If the engine is not running, start the background loop, which iteratively invokes `engine_step()` to process the waiting requests.
- Add the request to the engine's *RequestTracker*. On the next background loop, this request will be sent to the underlying engine. Also, a corresponding *AsyncStream* will be created.
- Wait for the request outputs from *AsyncStream* and yield them.

Example

```
>>> # Please refer to entrypoints/api_server.py for
>>> # the complete example.
>>>
>>> # initialize the engine and the example input
>>> engine = AsyncLLMEngine.from_engine_args(engine_args)
>>> example_input = {
>>>     "input": "What is LLM?",
>>>     "request_id": 0,
>>> }
>>>
>>> # start the generation
>>> results_generator = engine.encode(
>>>     example_input["input"],
>>>     PoolingParams(),
>>>     example_input["request_id"])
>>>
>>> # get the results
>>> final_output = None
>>> async for request_output in results_generator:
>>>     if await request.is_disconnected():
>>>         # Abort the request if the client disconnects.
>>>         await engine.abort(request_id)
>>>         # Return or raise an error
>>>         ...
>>>     final_output = request_output
>>>
>>> # Process and return the final output
>>> ...
```

async engine_step(*virtual_engine: int*) → bool

Kick the engine to process the waiting requests.

Returns True if there are in-progress requests.

classmethod from_engine_args(*engine_args: AsyncEngineArgs, start_engine_loop: bool = True, usage_context: UsageContext = UsageContext.ENGINE_CONTEXT, stat_loggers: Dict[str, StatLoggerBase] | None = None*) → *AsyncLLMEngine*

Creates an async LLM engine from the engine arguments.

async generate(*inputs: str | TextPrompt | TokensPrompt | ExplicitEncoderDecoderPrompt, sampling_params: SamplingParams, request_id: str, lora_request: LoRARequest | None = None, trace_headers: Mapping[str, str] | None = None, prompt_adapter_request: PromptAdapterRequest | None = None*) → *AsyncGenerator[RequestOutput, None]*

Generate outputs for a request.

Generate outputs for a request. This method is a coroutine. It adds the request into the waiting queue of the LLMEngine and streams the outputs from the LLMEngine to the caller.

Parameters

- **inputs** – The inputs to the LLM. See [PromptInputs](#) for more details about the format of each input.
- **sampling_params** – The sampling parameters of the request.
- **request_id** – The unique id of the request.
- **lora_request** – LoRA request to use for generation, if any.
- **trace_headers** – OpenTelemetry trace headers.
- **prompt_adapter_request** – Prompt Adapter request to use for generation, if any.

Yields

The output *RequestOutput* objects from the LLMEngine for the request.

Details:

- If the engine is not running, start the background loop, which iteratively invokes `engine_step()` to process the waiting requests.
- Add the request to the engine's *RequestTracker*. On the next background loop, this request will be sent to the underlying engine. Also, a corresponding *AsyncStream* will be created.
- Wait for the request outputs from *AsyncStream* and yield them.

Example

```
>>> # Please refer to entrypoints/api_server.py for
>>> # the complete example.
>>>
>>> # initialize the engine and the example input
>>> engine = AsyncLLMEngine.from_engine_args(engine_args)
>>> example_input = {
>>>     "prompt": "What is LLM?",
>>>     "stream": False, # assume the non-streaming case
>>>     "temperature": 0.0,
```

(continues on next page)

(continued from previous page)

```

>>>     "request_id": 0,
>>> }
>>>
>>> # start the generation
>>> results_generator = engine.generate(
>>>     example_input["prompt"],
>>>     SamplingParams(temperature=example_input["temperature"]),
>>>     example_input["request_id"])
>>>
>>> # get the results
>>> final_output = None
>>> async for request_output in results_generator:
>>>     if await request.is_disconnected():
>>>         # Abort the request if the client disconnects.
>>>         await engine.abort(request_id)
>>>         # Return or raise an error
>>>         ...
>>>     final_output = request_output
>>>
>>> # Process and return the final output
>>> ...

```

async get_decoding_config() → DecodingConfig
Get the decoding configuration of the vLLM engine.

async get_lora_config() → LoRAConfig
Get the lora configuration of the vLLM engine.

async get_model_config() → ModelConfig
Get the model configuration of the vLLM engine.

async get_parallel_config() → ParallelConfig
Get the parallel configuration of the vLLM engine.

async get_scheduler_config() → SchedulerConfig
Get the scheduling configuration of the vLLM engine.

property limit_concurrency: `int | None`
Maximum number of concurrently running requests.

shutdown_background_loop() → None
Shut down the background loop.

This method needs to be called during cleanup to remove references to *self* and properly GC the resources held by the async LLM engine (e.g., the executors as well as their resources).

start_background_loop() → None
Start the background loop.

1.43 vLLM Paged Attention

- Currently, vLLM utilizes its own implementation of a multi-head query attention kernel (`csrc/attention/attention_kernels.cu`). This kernel is designed to be compatible with vLLM’s paged KV caches, where the key and value cache are stored in separate blocks (note that this block concept differs from the GPU thread block. So in a later document, I will refer to vLLM paged attention block as “block”, while refer to GPU thread block as “thread block”).
- To achieve high performance, this kernel relies on a specially designed memory layout and access method, specifically when threads read data from global memory to shared memory. The purpose of this document is to provide a high-level explanation of the kernel implementation step by step, aiding those who wish to learn about the vLLM multi-head query attention kernel. After going through this document, users will likely have a better understanding and feel easier to follow the actual implementation.
- Please note that this document may not cover all details, such as how to calculate the correct index for the corresponding data or the dot multiplication implementation. However, after reading this document and becoming familiar with the high-level logic flow, it should be easier for you to read the actual code and understand the details.

1.43.1 Inputs

- The kernel function takes a list of arguments for the current thread to perform its assigned work. The three most important arguments are the input pointers `q`, `k_cache`, and `v_cache`, which point to query, key, and value data on global memory that need to be read and processed. The output pointer `out` points to global memory where the result should be written. These four pointers actually refer to multi-dimensional arrays, but each thread only accesses the portion of data assigned to it. I have omitted all other runtime parameters here for simplicity.

```
template<
typename scalar_t,
int HEAD_SIZE,
int BLOCK_SIZE,
int NUM_THREADS,
int PARTITION_SIZE = 0>
__device__ void paged_attention_kernel(
... // Other side args.
const scalar_t* __restrict__ out,           // [num_seqs, num_heads, max_num_partitions,
↪ head_size]
const scalar_t* __restrict__ q,           // [num_seqs, num_heads, head_size]
const scalar_t* __restrict__ k_cache,     // [num_blocks, num_kv_heads, head_size/x,
↪ block_size, x]
const scalar_t* __restrict__ v_cache,     // [num_blocks, num_kv_heads, head_size,
↪ block_size]
... // Other side args.
)
```

- There are also a list of template arguments above the function signature that are determined during compilation time. `scalar_t` represents the data type of the query, key, and value data elements, such as FP16. `HEAD_SIZE` indicates the number of elements in each head. `BLOCK_SIZE` refers to the number of tokens in each block. `NUM_THREADS` denotes the number of threads in each thread block. `PARTITION_SIZE` represents the number of tensor parallel GPUs (For simplicity, we assume this is 0 and tensor parallel is disabled).
- With these arguments, we need to perform a sequence of preparations. This includes calculating the current head index, block index, and other necessary variables. However, for now, we can ignore these preparations and proceed directly to the actual calculations. It will be easier to understand them once we grasp the entire flow.

1.43.2 Concepts

- Just before we dive into the calculation flow, I want to describe a few concepts that are needed for later sections. However, you may skip this section and return later if you encounter any confusing terminologies.
- **Sequence:** A sequence represents a client request. For example, the data pointed to by `q` has a shape of `[num_seqs, num_heads, head_size]`. That represents there are total `num_seqs` of query sequence data are pointed by `q`. Since this kernel is a single query attention kernel, each sequence only has one query token. Hence, the `num_seqs` equals the total number of tokens that are processed in the batch.
- **Context:** The context consists of the generated tokens from the sequence. For instance, `["What", "is", "your"]` are the context tokens, and the input query token is `"name"`. The model might generate the token `"?"`.
- **Vec:** The `vec` is a list of elements that are fetched and calculated together. For query and key data, the `vec` size (`VEC_SIZE`) is determined so that each thread group can fetch and calculate 16 bytes of data at a time. For value data, the `vec` size (`V_VEC_SIZE`) is determined so that each thread can fetch and calculate 16 bytes of data at a time. For example, if the `scalar_t` is FP16 (2 bytes) and `THREAD_GROUP_SIZE` is 2, the `VEC_SIZE` will be 4, while the `V_VEC_SIZE` will be 8.
- **Thread group:** The thread group is a small group of threads (`THREAD_GROUP_SIZE`) that fetches and calculates one query token and one key token at a time. Each thread handles only a portion of the token data. The total number of elements processed by one thread group is referred as `x`. For example, if the thread group contains 2 threads and the head size is 8, then thread 0 handles the query and key elements at index 0, 2, 4, 6, while thread 1 handles the elements at index 1, 3, 5, 7.
- **Block:** The key and value cache data in vLLM are split into blocks. Each block stores data for a fixed number (`BLOCK_SIZE`) of tokens at one head. Each block may contain only a portion of the whole context tokens. For example, if the block size is 16 and the head size is 128, then for one head, one block can store $16 * 128 = 2048$ elements.
- **Warp:** A warp is a group of 32 threads (`WARP_SIZE`) that execute simultaneously on a stream multiprocessor (SM). In this kernel, each warp processes the calculation between one query token and key tokens of one entire block at a time (it may process multiple blocks in multiple iterations). For example, if there are 4 warps and 6 blocks for one context, the assignment would be like warp 0 handles the 0th, 4th blocks, warp 1 handles the 1st, 5th blocks, warp 2 handles the 2nd block and warp 3 handles the 3rd block.
- **Thread block:** A thread block is a group of threads (`NUM_THREADS`) that can access the same shared memory. Each thread block contains multiple warps (`NUM_WARPS`), and in this kernel, each thread block processes the calculation between one query token and key tokens of a whole context.
- **Grid:** A grid is a collection of thread blocks and defines the shape of the collection. In this kernel, the shape is (`num_heads, num_seqs, max_num_partitions`). Therefore, each thread block only handles the calculation for one head, one sequence, and one partition.

1.43.3 Query

- This section will introduce how query data is stored in memory and fetched by each thread. As mentioned above, each thread group fetches one query token data, while each thread itself only handles a part of one query token data. Within each warp, every thread group will fetch the same query token data, but will multiply it with different key token data.

```
const scalar_t* q_ptr = q + seq_idx * q_stride + head_idx * HEAD_SIZE;
```

- Each thread defines its own `q_ptr` which points to the assigned query token data on global memory. For example, if `VEC_SIZE` is 4 and `HEAD_SIZE` is 128, the `q_ptr` points to data that contains total of 128 elements divided into $128 / 4 = 32$ vecs.

Fig. 2: Query data of one token at one head

Fig. 3: `q_vecs` for one thread group

```
__shared__ Q_vec q_vecs[THREAD_GROUP_SIZE][NUM_VECS_PER_THREAD];
```

- Next, we need to read the global memory data pointed to by `q_ptr` into shared memory as `q_vecs`. It is important to note that each `vecs` is assigned to a different row. For example, if the `THREAD_GROUP_SIZE` is 2, thread 0 will handle the 0th row `vecs`, while thread 1 handles the 1st row `vecs`. By reading the query data in this way, neighboring threads like thread 0 and thread 1 can read neighbor memory, achieving the memory coalescing to improve performance.

1.43.4 Key

- Similar to the “Query” section, this section introduces memory layout and assignment for keys. While each thread group only handle one query token one kernel run, it may handle multiple key tokens across multiple iterations. Meanwhile, each warp will process multiple blocks of key tokens in multiple iterations, ensuring that all context tokens are processed by the entire thread group after the kernel run. In this context, “handle” refers to performing the dot multiplication between query data and key data.

```
const scalar_t* k_ptr = k_cache + physical_block_number * kv_block_stride
    + kv_head_idx * kv_head_stride
    + physical_block_offset * x;
```

- Unlike to `q_ptr`, `k_ptr` in each thread will point to different key token at different iterations. As shown above, that `k_ptr` points to key token data based on `k_cache` at assigned block, assigned head and assigned token.
- The diagram above illustrates the memory layout for key data. It assumes that the `BLOCK_SIZE` is 16, `HEAD_SIZE` is 128, `x` is 8, `THREAD_GROUP_SIZE` is 2, and there are a total of 4 warps. Each rectangle represents all the elements for one key token at one head, which will be processed by one thread group. The left half shows the total 16 blocks of key token data for warp 0, while the right half represents the remaining key token data for other warps or iterations. Inside each rectangle, there are a total 32 `vecs` (128 elements for one token) that will be processed by 2 threads (one thread group) separately.

```
K_vec k_vecs[NUM_VECS_PER_THREAD]
```

- Next, we need to read the key token data from `k_ptr` and store them on register memory as `k_vecs`. We use register memory for `k_vecs` because it will only be accessed by one thread once, whereas `q_vecs` will be accessed by multiple threads multiple times. Each `k_vecs` will contain multiple vectors for later calculation. Each `vec` will be set at each inner iteration. The assignment of `vecs` allows neighboring threads in a warp to read neighboring memory together, which again promotes the memory coalescing. For instance, thread 0 will read

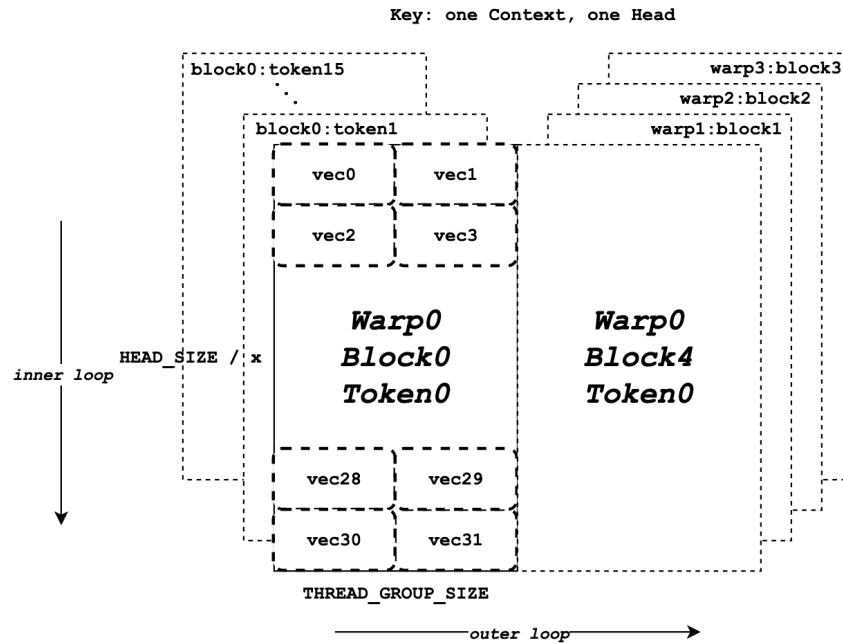

Fig. 4: Key data of all context tokens at one head

Fig. 5: k_vecs for one thread

vec 0, while thread 1 will read vec 1. In the next inner loop, thread 0 will read vec 2, while thread 1 will read vec 3, and so on.

- You may still be a little confused about the overall flow. Don't worry, please keep reading the next "QK" section. It will illustrate the query and key calculation flow in a clearer and higher-level manner.

1.43.5 QK

- As shown the pseudo code below, before the entire for loop block, we fetch the query data for one token and store it in `q_vecs`. Then, in the outer for loop, we iterate through different `k_ptrs` that point to different tokens and prepare the `k_vecs` in the inner for loop. Finally, we perform the dot multiplication between the `q_vecs` and each `k_vecs`.

```

q_vecs = ...
for ... {
    k_ptr = ...
    for ... {
        k_vecs[i] = ...
    }
    ...
    float qk = scale * Qk_dot<scalar_t, THREAD_GROUP_SIZE>::dot(q_vecs[thread_group_
↪offset], k_vecs);
}

```

- As mentioned before, for each thread, it only fetches part of the query and key token data at a time. However, there will be a cross thread group reduction happen in the `Qk_dot<>::dot`. So `qk` returned here is not just between part of the query and key token dot multiplication, but actually a full result between entire query and key token data.
- For example, if the value of `HEAD_SIZE` is 128 and `THREAD_GROUP_SIZE` is 2, each thread's `k_vecs` will contain total 64 elements. However, the returned `qk` is actually the result of dot multiplication between 128 query elements and 128 key elements. If you want to learn more about the details of the dot multiplication and reduction, you may refer to the implementation of `Qk_dot<>::dot`. However, for the sake of simplicity, I will not cover it in this document.

1.43.6 Softmax

- Next, we need to calculate the normalized softmax for all `qks`, as shown above, where each x represents a `qk`. To do this, we must obtain the reduced value of `qk_max(m(x))` and the `exp_sum(l(x))` of all `qks`. The reduction should be performed across the entire thread block, encompassing results between the query token and all context key tokens.

$$\begin{aligned}
 m(x) &:= \max_i x_i \\
 f(x) &:= [e^{x_1 - m(x)} \quad \dots \quad e^{x_B - m(x)}] \\
 \ell(x) &:= \sum_i f(x)_i \\
 \text{softmax}(x) &:= \frac{f(x)}{\ell(x)}
 \end{aligned}$$

qk_max and logits

- Just right after we get the qk result, we can set the temporary logits result with qk (In the end, the logits should store the normalized softmax result). Also we can compare and collect the qk_max for all qks that are calculated by current thread group.

```
if (thread_group_offset == 0) {
    const bool mask = token_idx >= context_len;
    logits[token_idx - start_token_idx] = mask ? 0.f : qk;
    qk_max = mask ? qk_max : fmaxf(qk_max, qk);
}
```

- Please note that the logits here is on shared memory, so each thread group will set the fields for its own assigned context tokens. Overall, the size of logits should be number of context tokens.

```
for (int mask = WARP_SIZE / 2; mask >= THREAD_GROUP_SIZE; mask /= 2) {
    qk_max = fmaxf(qk_max, VLLM_SHFL_XOR_SYNC(qk_max, mask));
}

if (lane == 0) {
    red_smem[warp_idx] = qk_max;
}
```

- Then we need to get the reduced qk_max across each warp. The main idea is to make threads in warp to communicate with each other and get the final max qk.

```
for (int mask = NUM_WARPS / 2; mask >= 1; mask /= 2) {
    qk_max = fmaxf(qk_max, VLLM_SHFL_XOR_SYNC(qk_max, mask));
}
qk_max = VLLM_SHFL_SYNC(qk_max, 0);
```

- Finally, we can get the reduced qk_max from whole thread block by compare the qk_max from all warps in this thread block. Then we need to broadcast the final result to each thread.

exp_sum

- Similar to qk_max, we need to get the reduced sum value from the entire thread block too.

```
for (int i = thread_idx; i < num_tokens; i += NUM_THREADS) {
    float val = __expf(logits[i] - qk_max);
    logits[i] = val;
    exp_sum += val;
}
...
exp_sum = block_sum<NUM_WARPS>(&red_smem[NUM_WARPS], exp_sum);
```

- Firstly, sum all exp values from each thread group, and meanwhile, convert each entry of logits from qk to $\exp(qk - qk_max)$. Please note, the qk_max here is already the max qk across the whole thread block. And then we can do reduction for exp_sum across whole thread block just like the qk_max.

```
const float inv_sum = __fdivdef(1.f, exp_sum + 1e-6f);
for (int i = thread_idx; i < num_tokens; i += NUM_THREADS) {
    logits[i] *= inv_sum;
}
```

- Finally, with the reduced `qk_max` and `exp_sum`, we can obtain the final normalized softmax result as `logits`. This `logits` variable will be used for dot multiplication with the value data in later steps. Now, it should store the normalized softmax result of `qk` for all assigned context tokens.

1.43.7 Value

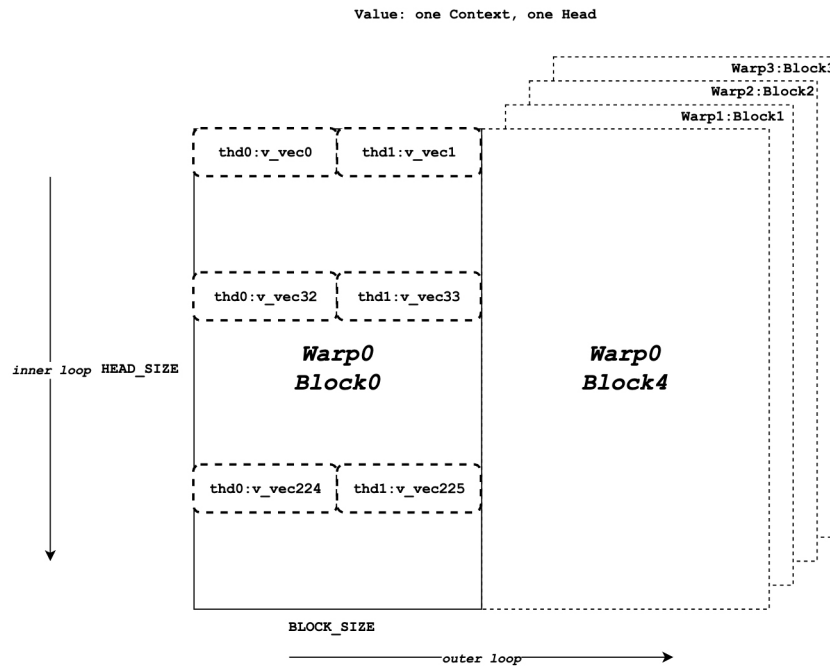

Fig. 6: Value data of all context tokens at one head

Fig. 7: `logits_vec` for one thread

- Now we need to retrieve the value data and perform dot multiplication with `logits`. Unlike query and key, there is no thread group concept for value data. As shown in diagram, different from key token memory layout, elements from the same column correspond to the same value token. For one block of value data, there are `HEAD_SIZE` of rows and `BLOCK_SIZE` of columns that are split into multiple `v_vecs`.
- Each thread always fetches `V_VEC_SIZE` elements from the same `V_VEC_SIZE` of tokens at a time. As a result, a single thread retrieves multiple `v_vecs` from different rows and the same columns through multiple inner iterations. For each `v_vec`, it needs to be dot multiplied with the corresponding `logits_vec`, which is also `V_VEC_SIZE` elements from `logits`. Overall, with multiple inner iterations, each warp will process one block of value tokens. And with multiple outer iterations, the whole context value tokens are processed

```
float accs[NUM_ROWS_PER_THREAD];
for ... { // Iteration over different blocks.
```

(continues on next page)

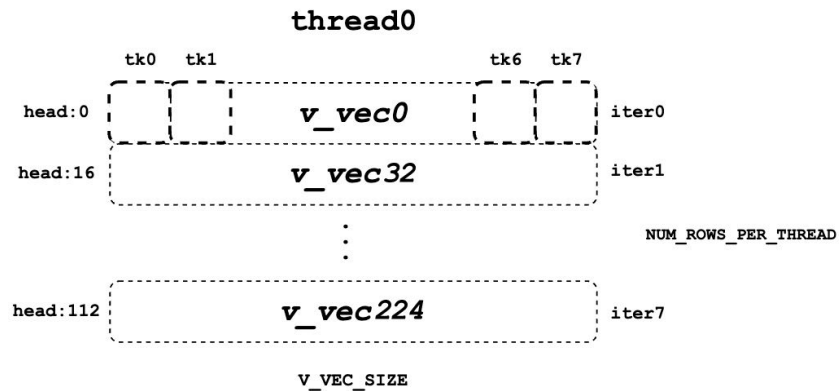

Fig. 8: List of v_vec for one thread

(continued from previous page)

```

logits_vec = ...
for ... { // Iteration over different rows.
    v_vec = ...
    ...
    accs[i] += dot(logits_vec, v_vec);
}
}

```

- As shown in the above pseudo code, in the outer loop, similar to `k_ptr`, `logits_vec` iterates over different blocks and reads `V_VEC_SIZE` elements from `logits`. In the inner loop, each thread reads `V_VEC_SIZE` elements from the same tokens as a `v_vec` and performs dot multiplication. It is important to note that in each inner iteration, the thread fetches different head position elements for the same tokens. The dot result is then accumulated in `accs`. Therefore, each entry of `accs` is mapped to a head position assigned to the current thread.
- For example, if `BLOCK_SIZE` is 16 and `V_VEC_SIZE` is 8, each thread fetches 8 value elements for 8 tokens at a time. Each element is from different tokens at the same head position. If `HEAD_SIZE` is 128 and `WARP_SIZE` is 32, for each inner loop, a warp needs to fetch `WARP_SIZE * V_VEC_SIZE = 256` elements. This means there are a total of $128 * 16 / 256 = 8$ inner iterations for a warp to handle a whole block of value tokens. And each `accs` in each thread contains 8 elements that accumulated at 8 different head positions. For the thread 0, the `accs` variable will have 8 elements, which are 0th, 32th ... 224th elements of a value head that are accumulated from all assigned 8 tokens.

1.43.8 LV

- Now, we need to perform reduction for `accs` within each warp. This process allows each thread to accumulate the `accs` for the assigned head positions of all tokens in one block.

```

for (int i = 0; i < NUM_ROWS_PER_THREAD; i++) {
    float acc = accs[i];
    for (int mask = NUM_V_VECS_PER_ROW / 2; mask >= 1; mask /= 2) {
        acc += VLLM_SHFL_XOR_SYNC(acc, mask);
    }
    accs[i] = acc;
}
}

```

- Next, we perform reduction for accs across all warps, allowing each thread to have the accumulation of accs for the assigned head positions of all context tokens. Please note that each accs in every thread only stores the accumulation for a portion of elements of the entire head for all context tokens. However, overall, all results for output have been calculated but are just stored in different thread register memory.

```
float* out_smem = reinterpret_cast<float*>(shared_mem);
for (int i = NUM_WARPS; i > 1; i /= 2) {
    // Upper warps write to shared memory.
    ...
    float* dst = &out_smem[(warp_idx - mid) * HEAD_SIZE];
    for (int i = 0; i < NUM_ROWS_PER_THREAD; i++) {
        ...
        dst[row_idx] = accs[i];
    }

    // Lower warps update the output.
    const float* src = &out_smem[warp_idx * HEAD_SIZE];
    for (int i = 0; i < NUM_ROWS_PER_THREAD; i++) {
        ...
        accs[i] += src[row_idx];
    }

    // Write out the accs.
}
}
```

1.43.9 Output

- Now we can write all of calculated result from local register memory to final output global memory.

```
scalar_t* out_ptr = out + seq_idx * num_heads * max_num_partitions * HEAD_SIZE
                + head_idx * max_num_partitions * HEAD_SIZE
                + partition_idx * HEAD_SIZE;
```

- First, we need to define the out_ptr variable, which points to the start address of the assigned sequence and assigned head.

```
for (int i = 0; i < NUM_ROWS_PER_THREAD; i++) {
    const int row_idx = lane / NUM_V_VECS_PER_ROW + i * NUM_ROWS_PER_ITER;
    if (row_idx < HEAD_SIZE && lane % NUM_V_VECS_PER_ROW == 0) {
        from_float(*(out_ptr + row_idx), accs[i]);
    }
}
}
```

- Finally, we need to iterate over different assigned head positions and write out the corresponding accumulated result based on the out_ptr.

1.44 Input Processing

Each model can override parts of vLLM's *input processing pipeline* via `INPUT_REGISTRY` and `MULTIMODAL_REGISTRY`.

Currently, this mechanism is only utilized in *multi-modal* models for preprocessing multi-modal input data in addition to input prompt, but it can be extended to text-only language models when needed.

1.44.1 Guides

Input Processing Pipeline

1. Input data is passed to `LLMEngine` (or `AsyncLLMEngine`).
2. Tokenize the data if necessary.
3. Process the inputs using `INPUT_REGISTRY.process_input`.
 - For example, add placeholder tokens to reserve KV cache for multi-modal embeddings.
4. Send the processed inputs to `ExecutorBase`.
5. Distribute the inputs via `WorkerBase` to `ModelRunnerBase`.
6. If the data contains multi-modal data, convert it into keyword arguments using `MULTIMODAL_REGISTRY.map_input`.
 - For example, convert a `PIL.Image.Image` input to its pixel values for a vision model.

1.44.2 Module Contents

LLM Engine Inputs

`class vllm.inputs.LLMInputs`

Bases: `TypedDict`

The inputs in `LLMEngine` before they are passed to the model executor.

This specifies the data required for decoder-only models.

`multi_modal_data: typing_extensions.NotRequired[MultiModalDataDict | None]`

Optional multi-modal data to pass to the model, if the model supports it.

`prompt: typing_extensions.NotRequired[str | None]`

The original prompt text corresponding to the token IDs, if available.

`prompt_token_ids: List[int]`

The token IDs of the prompt.

Registry

`vllm.inputs.INPUT_REGISTRY = <vllm.inputs.registry.InputRegistry object>`

The global `InputRegistry` which is used by `LLMEngine` to dispatch data processing according to the target model.

See also:

Input Processing Pipeline

class `vllm.inputs.registry.DummyDataFactory(*args, **kwargs)`

Bases: `Protocol`

class `vllm.inputs.registry.InputContext(model_config: ModelConfig)`

Contains information about the model which may be used to modify the inputs.

get_hf_config(*hf_config_type: Type[C] = PretrainedConfig*) → *C*

Get the HuggingFace configuration (`transformers.PretrainedConfig`) of the model, additionally checking its type.

Raises

TypeError – If the model is not of the specified type.

get_hf_image_processor_config() → `Dict[str, Any]`

Get the HuggingFace image processor configuration of the model.

model_config: ModelConfig

The configuration of the model.

`vllm.inputs.registry.InputProcessor`

Preprocess the inputs to the model.

alias of `Callable[[InputContext, LLMInputs], LLMInputs]`

class `vllm.inputs.registry.InputRegistry`

A registry to dispatch data processing according to the target model.

create_input_processor(*model_config: ModelConfig*)

Create an input processor (see `process_input()`) for a specific model.

dummy_data_for_profiling(*model_config: ModelConfig, seq_len: int, mm_registry:*

`MultiModalRegistry`) → `Tuple[SequenceData, MultiModalDataDict | None]`

Create dummy data for profiling the memory usage of a model.

The model is identified by `model_config`.

See also:

Enabling Multimodal Inputs

Note: This should be called after `init_mm_limits_per_prompt()`.

process_input(*model_config: ModelConfig, inputs: LLMInputs*) → `LLMInputs`

Apply an input processor to an instance of model inputs.

The model is identified by `model_config`.

See also:

Input Processing Pipeline

register_dummy_data(*factory*: DummyDataFactory)

Register a dummy data factory to a model class.

During memory profiling, the provided function is invoked to create dummy data to be inputted into the model. The resulting memory usage should be an upper bound of what the model would use at inference time.

register_input_processor(*processor*: Callable[[InputContext, LLMInputs], LLMInputs])

Register an input processor to a model class.

The provided function is invoked on each input to the model. This happens before `map_input()`.

See also:

Input Processing Pipeline

1.45 Multi-Modality

vLLM provides experimental support for multi-modal models through the `vllm.multimodal` package.

Multi-modal inputs can be passed alongside text and token prompts to *supported models* via the `multi_modal_data` field in `vllm.inputs.PromptInputs`.

Currently, vLLM only has built-in support for image data. You can extend vLLM to process additional modalities by following *this guide*.

Looking to add your own multi-modal model? Please follow the instructions listed *here*.

1.45.1 Guides

Adding a Multimodal Plugin

This document teaches you how to add a new modality to vLLM.

Each modality in vLLM is represented by a `MultiModalPlugin` and registered to `MULTIMODAL_REGISTRY`. For vLLM to recognize a new modality type, you have to create a new plugin and then pass it to `register_plugin()`.

The remainder of this document details how to define custom `MultiModalPlugin`s.

Note: This article is a work in progress.

1.45.2 Module Contents

Registry

`vllm.multimodal.MULTIMODAL_REGISTRY = <vllm.multimodal.registry.MultiModalRegistry object>`

The global `MultiModalRegistry` is used by model runners to dispatch data processing according to its modality and the target model.

See also:

Input Processing Pipeline

```
class vllm.multimodal.MultiModalRegistry(*plugins: Sequence[MultiModalPlugin] =
                                         DEFAULT_PLUGINS)
```

A registry that dispatches data processing to the *MultiModalPlugin* for each modality.

```
create_input_mapper(model_config: ModelConfig)
```

Create an input mapper (see *map_input()*) for a specific model.

```
get_max_multimodal_tokens(model_config: ModelConfig) → int
```

Get the maximum number of multi-modal tokens for profiling the memory usage of a model.

See *MultiModalPlugin.get_max_multimodal_tokens()* for more details.

Note: This should be called after *init_mm_limits_per_prompt()*.

```
get_mm_limits_per_prompt(model_config: ModelConfig) → Mapping[str, int]
```

Get the maximum number of multi-modal input instances for each modality that are allowed per prompt for a model class.

Note: This should be called after *init_mm_limits_per_prompt()*.

```
init_mm_limits_per_prompt(model_config: ModelConfig) → None
```

Initialize the maximum number of multi-modal input instances for each modality that are allowed per prompt for a model class.

```
map_input(model_config: ModelConfig, data: MultiModalDataBuiltins | Mapping[str, object | List[object]])
          → MultiModalInputs
```

Apply an input mapper to the data passed to the model.

The data belonging to each modality is passed to the corresponding plugin which in turn converts the data into keyword arguments via the input mapper registered for that model.

See *MultiModalPlugin.map_input()* for more details.

Note: This should be called after *init_mm_limits_per_prompt()*.

```
register_image_input_mapper(mapper: Callable[[InputContext, object | List[object]],
                             MultiModalInputs] | None = None)
```

Register an input mapper for image data to a model class.

See *MultiModalPlugin.register_input_mapper()* for more details.

```
register_input_mapper(data_type_key: str, mapper: Callable[[InputContext, object | List[object]],
                      MultiModalInputs] | None = None)
```

Register an input mapper for a specific modality to a model class.

See *MultiModalPlugin.register_input_mapper()* for more details.

```
register_max_image_tokens(max_mm_tokens: int | Callable[[InputContext], int] | None = None)
```

Register the maximum number of image tokens, corresponding to a single image, that are passed to the language model for a model class.

register_max_multimodal_tokens(*data_type_key*: str, *max_mm_tokens*: int | Callable[[InputContext], int] | None = None)

Register the maximum number of tokens, corresponding to a single instance of multimodal data belonging to a specific modality, that are passed to the language model for a model class.

register_plugin(*plugin*: MultiModalPlugin) → None

Register a multi-modal plugin so it can be recognized by vLLM.

See also:

Adding a Multimodal Plugin

Base Classes

vllm.multimodal.NestedTensors

The central part of internal API.

This represents a generic version of type ‘origin’ with type arguments ‘params’. There are two kind of these aliases: user defined and special. The special ones are wrappers around builtin collections and ABCs in collections.abc. These must have ‘name’ always set. If ‘inst’ is False, then the alias can’t be instantiated, this is used by e.g. typing.List and typing.Dict.

alias of Union[List[NestedTensors], List[Tensor], Tensor]

vllm.multimodal.BatchedTensorInputs

The central part of internal API.

This represents a generic version of type ‘origin’ with type arguments ‘params’. There are two kind of these aliases: user defined and special. The special ones are wrappers around builtin collections and ABCs in collections.abc. These must have ‘name’ always set. If ‘inst’ is False, then the alias can’t be instantiated, this is used by e.g. typing.List and typing.Dict.

alias of Dict[str, Union[List[NestedTensors], List[Tensor], Tensor]]

final class vllm.multimodal.MultiModalDataBuiltins(*args, **kwargs)

Bases: dict

Modality types that are predefined by vLLM.

audio: Tuple[ndarray, int | float] | List[Tuple[ndarray, int | float]]

The input audio item(s) and corresponding sampling rate(s).

image: Image | List[Image]

The input image(s).

vllm.multimodal.MultiModalDataDict

The central part of internal API.

This represents a generic version of type ‘origin’ with type arguments ‘params’. There are two kind of these aliases: user defined and special. The special ones are wrappers around builtin collections and ABCs in collections.abc. These must have ‘name’ always set. If ‘inst’ is False, then the alias can’t be instantiated, this is used by e.g. typing.List and typing.Dict.

alias of Union[MultiModalDataBuiltins, Mapping[str, Union[object, List[object]]]]

class vllm.multimodal.MultiModalInputs(dict=None, /, **kwargs)

Bases: _MultiModalInputsBase

A dictionary that represents the keyword arguments to `forward()`.

```
static batch(inputs_list: List[MultiModalInputs]) → Dict[str, List[List[NestedTensors] |
List[torch.Tensor] | torch.Tensor] | List[torch.Tensor] | torch.Tensor]
```

Batch multiple inputs together into a dictionary.

The resulting dictionary has the same keys as the inputs. If the corresponding value from each input is a tensor and they all share the same shape, the output value is a single batched tensor; otherwise, the output value is a list containing the original value from each input.

```
class vllm.multimodal.MultiModalPlugin
```

Bases: [ABC](#)

Base class that defines data processing logic for a specific modality.

In particular, we adopt a registry pattern to dispatch data processing according to the model being used (considering that different models may process the same data differently). This registry is in turn used by [MultiModalRegistry](#) which acts at a higher level (i.e., the modality of the data).

See also:

[Adding a Multimodal Plugin](#)

```
abstract get_data_key() → str
```

Get the data key corresponding to the modality.

```
get_max_multimodal_tokens(model_config: ModelConfig) → int
```

Get the maximum number of multi-modal tokens for profiling the memory usage of a model.

If this registry is not applicable to the model, 0 is returned.

The model is identified by `model_config`.

See also:

[Enabling Multimodal Inputs](#)

```
map_input(model_config: ModelConfig, data: object | List[object]) → MultiModalInputs
```

Transform the data into a dictionary of model inputs using the input mapper registered for that model.

The model is identified by `model_config`.

Raises

TypeError – If the data type is not supported.

See also:

- [Input Processing Pipeline](#)
- [Enabling Multimodal Inputs](#)

```
register_input_mapper(mapper: Callable[[InputContext, object | List[object]], MultiModalInputs] |
None = None)
```

Register an input mapper to a model class.

When the model receives input data that matches the modality served by this plugin (see [get_data_key\(\)](#)), the provided function is invoked to transform the data into a dictionary of model inputs.

If `None` is provided, then the default input mapper is used instead.

See also:

- [Input Processing Pipeline](#)
- [Enabling Multimodal Inputs](#)

register_max_multimodal_tokens(*max_mm_tokens*: *int* | *Callable*[[*InputContext*], *int*] | *None* = *None*)

Register the maximum number of tokens, corresponding to a single instance of multimodal data, that are passed to the language model for a model class.

If *None* is provided, then the default calculation is used instead.

See also:

Enabling Multimodal Inputs

Image Classes

class `vllm.multimodal.image.ImagePlugin`

Bases: *MultiModalPlugin*

Plugin for image data.

get_data_key() → *str*

Get the data key corresponding to the modality.

1.46 Dockerfile

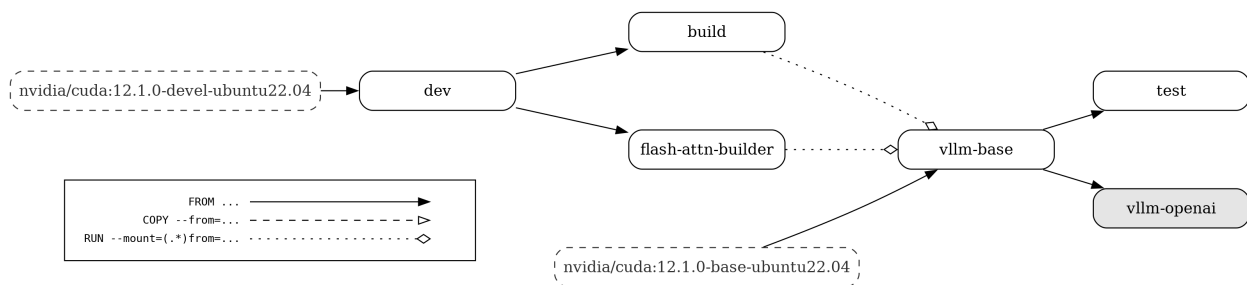

See [here](#) for the main Dockerfile to construct the image for running an OpenAI compatible server with vLLM. More information about deploying with Docker can be found [here](#).

Below is a visual representation of the multi-stage Dockerfile. The build graph contains the following nodes:

- All build stages
- The default build target (highlighted in grey)
- External images (with dashed borders)

The edges of the build graph represent:

- FROM ... dependencies (with a solid line and a full arrow head)
- COPY --from=... dependencies (with a dashed line and an empty arrow head)
- RUN --mount=(.*)from=... dependencies (with a dotted line and an empty diamond arrow head)

Made using: <https://github.com/patrickhoefler/dockerfilegraph>

Commands to regenerate the build graph (make sure to run it **from the `root` directory of the vLLM repository** where the dockerfile is present):

```
dockerfilegraph -o png --legend --dpi 200 --max-label-length 50 --filename Dockerfile
```

or in case you want to run it directly with the docker image:

```
docker run \  
  --rm \  
  --user "$(id -u):$(id -g)" \  
  --workdir /workspace \  
  --volume "$(pwd)":/workspace \  
  ghcr.io/patrickhoefler/dockerfilegraph:alpine \  
  --output png \  
  --dpi 200 \  
  --max-label-length 50 \  
  --filename Dockerfile \  
  --legend
```

(To run it for a different file, you can pass in a different argument to the flag `-filename`.)

1.47 Profiling vLLM

We support tracing vLLM workers using the `torch.profiler` module. You can enable tracing by setting the `VLLM_TORCH_PROFILER_DIR` environment variable to the directory where you want to save the traces: `VLLM_TORCH_PROFILER_DIR=/mnt/traces/`

The OpenAI server also needs to be started with the `VLLM_TORCH_PROFILER_DIR` environment variable set.

When using `benchmarks/benchmark_serving.py`, you can enable profiling by passing the `--profile` flag.

Warning: Only enable profiling in a development environment.

Traces can be visualized using <https://ui.perfetto.dev/>.

Tip: Only send a few requests through vLLM when profiling, as the traces can get quite large. Also, no need to untar the traces, they can be viewed directly.

Tip: To stop the profiler - it flushes out all the profile trace files to the directory. This takes time, for example for about 100 requests worth of data for a llama 70b, it takes about 10 minutes to flush out on a H100. Set the env variable `VLLM_RPC_GET_DATA_TIMEOUT_MS` to a big number before you start the server. Say something like 30 minutes. `export VLLM_RPC_GET_DATA_TIMEOUT_MS=1800000`

1.48 Example commands and usage:

1.48.1 Offline Inference:

Refer to `examples/offline_inference_with_profiler.py` for an example.

1.48.2 OpenAI Server:

```
VLLM_TORCH_PROFILER_DIR=./vllm_profile python -m vllm.entrypoints.openai.api_server --  
↪model meta-llama/Meta-Llama-3-70B
```

benchmark_serving.py:

```
python benchmarks/benchmark_serving.py --backend vllm --model meta-llama/Meta-Llama-3-  
↪70B --dataset-name sharegpt --dataset-path sharegpt.json --profile --num-prompts 2
```

1.49 vLLM Meetups

We host regular meetups in San Francisco Bay Area every 2 months. We will share the project updates from the vLLM team and have guest speakers from the industry to share their experience and insights. Please find the materials of our previous meetups below:

- [The sixth vLLM meetup](#), with NVIDIA, September 9th 2024. [\[Slides\]](#)
- [The fifth vLLM meetup](#), with AWS, July 24th 2024. [\[Slides\]](#)
- [The fourth vLLM meetup](#), with Cloudflare and BentoML, June 11th 2024. [\[Slides\]](#)
- [The third vLLM meetup](#), with Roblox, April 2nd 2024. [\[Slides\]](#)
- [The second vLLM meetup](#), with IBM Research, January 31st 2024. [\[Slides\]](#) [\[Video \(vLLM Update\)\]](#) [\[Video \(IBM Research & torch.compile\)\]](#)
- [The first vLLM meetup](#), with a16z, October 5th 2023. [\[Slides\]](#)

We are always looking for speakers and sponsors at San Francisco Bay Area and potentially other locations. If you are interested in speaking or sponsoring, please contact us at vllm-questions@lists.berkeley.edu.

1.50 Sponsors

vLLM is a community project. Our compute resources for development and testing are supported by the following organizations. Thank you for your support!

- a16z
- AMD
- Anyscale
- AWS
- Crusoe Cloud
- Databricks
- DeepInfra
- Dropbox
- Google Cloud
- Lambda Lab
- NVIDIA

- Replicate
- Roblox
- RunPod
- Sequoia Capital
- Skywork AI
- Trainy
- UC Berkeley
- UC San Diego
- ZhenFund

We also have an official fundraising venue through [OpenCollective](#). We plan to use the fund to support the development, maintenance, and adoption of vLLM.
